The division of human life into periods for legal purposes is naturally more sharp and definite than it can be for physiological purposes. In Roman law the legal divisions were (1) *infantia* lasting till the close of the seventh year; (2) the period between *infantia* and *pubertas,* males becoming *puberes* at 14 and females at 12; (3) *adolescentia,* the period between puberty and majority; and (4) the period after the 25th year, when males become *majores.* By English law, life is divided into two main periods—*infancy,* which lasts in both sexes until the 21st year, and manhood or womanhood. The period of infancy, again, is divided into several stages, marked by the growing development both of rights and obligations. Thus at 12 years of age a male may take the oath of allegiance; at 14 both sexes are held to have arrived at years of discretion, and may therefore choose guardians, give evidence, and consent or disagree to a marriage. A female has the last privilege from the 12th year, but the marriage cannot be celebrated until the majority of the parties without the consent of parents or guardians. At 21 both males and females obtain their full legal rights and become liable to all legal obligations Thus both sexes may enter parliament and be called to the bar, upon attaining majority. In the Church of England, however, a candidate for deacon's orders must be 23 (in the Roman Catholic Church, 22), and for priest's orders 24 years of age; and no clergyman is eligible for a bishopric under 30. In Scotland infancy is not a legal term. The time previous to majority, which, as in England, is reached by both sexes at 21, is divided into two stages: *pupilage* lasts until the attainment of puberty, which the law fixes at 14 in males and 12 in females; *minority* lasts from these ages respectively until 21. *Minority* obviously corresponds in some degree to the English *years of discretion,* but a Scottish minor has more personal rights than an English infant in the last stage of his infancy, *e.g.,* he may dispose by will of movable property, make contracts, including that of marriage, carry on trade and become liable to be declared a bankrupt. Throughout the British Empire the age of majority is usually 21, but the

nubile age is 20 in the Channel Islands; 18 in New Brunswick and Ontario; 18 for females in the North-West Territories and 15 for native females in Fiji. In Belgium and France the age of majority is 21, and the nubile age 18 for males and 15 for females, but marriage cannot be contracted without the consent of the parents or guardians if the parties are under 25. The age of majority is in Argentina 22; in Chile, Spain and Austria 24; in China 20; in Brazil, Denmark, Holland, Germany, Greece, Italy, Mexico, Norway, Peru, the Philippines, Poland, Portugal, Rumania, Sweden, Switzerland and Tunis, 21. In Denmark the nubile age is 18 for males and 16 for females; in Germany 20 for males and 16 for females, subject to the consent of the parents or guardians, and without such consent the males must be 25 and the females 24. But a person of 18 may be declared of full age by a competent court. In Spain majority is reached at 23; the nubile age is 18 for males and 16 for females. In Greece the nubile age is 16 for males and 14 for females; in Holland 18 for males and 16 for females; in Italy 18 for males and 15 for females; in Switzerland 21 for males and 19 for females, but the canton authorities may in extraordinary cases reduce these figures to 19 and 18 respectively. Marriage by minors is subject to the consent of their parents or guardians.

By the constitution of the United States the President must be not less than 35; a senator not less than 30, and a representative not less than 25 years of age. The age of majority, as a rule, is 21 for both males and females, but in Arkansas, California, Colorado, Dakota, Idaho, Illinois, Iowa, Kansas, Maryland, Minnesota, Missouri, Nebraska, Nevada, Ohio, Oregon, Vermont and Washington females attain majority at 18. In Maryland, Oregon, and Texas a female attains majority upon marriage. In Iowa, Texas and Louisiana both males and females attain majority upon marriage, and in Washington a female minor married to a male of age is regarded as herself of full age. (H. H. L. B.)

**AGE GRADES** means a system of compulsory association or classification by age and sex, whereby groups of coevals are admitted by a series of initiatory rites of varying complexity, including generally the payment of a due, into a tribal association with definite functions both within the age group itself and in relation to the tribe as a whole, promotion to higher degrees, where such exist, being at regular intervals jointly compulsory on all the individuals comprising a group.

Though superficially resembling secret societies (*q.v.*), and though the ritual of initiation and subsequent ceremonies and esoteric beliefs are secret where a knowledge of them is confined to those who have been initiated and is moreover commensurate with the degree of their initiation, age grades are differentiated from other forms of association, including secret societies, by the following distinctive features: (1) Admission depends primarily on age and is associated with puberty rites. (2) Every member of the tribe must be affiliated to the system at the proper age. (3) There is no individual admission, but groups of coevals are jointly initiated. (4) Promotion to higher degrees of initiation is similarly compulsory and automatic with the passage of years, even when fees have to be paid or further rites have to be undergone. (5) The system is strictly unilateral, confined to males, though a corresponding institution for females may exist but, where it exists, functions independently. (6) The system is democratic.

Primitive societies are conspicuously divided vertically into families and clans and are horizontally stratified by a variety of associations: religious, occupational, political, social, and so on. Distinction by age and sex cuts across the bonds of consanguinity and creates a new orientation of social activity. Mere classification by age or sex, however, does not of itself indicate an age grade, for a variety of other factors is involved. A physiological classification of a tribe into boys, youths, adults and old men, with their feminine counterparts, stereotyped by custom into a conventional nomenclature, often lacks the distinctive sociological features of an age grade: just as we find puberty rites in almost all primitive societies, whereas age grades, though associated with puberty ceremonies and retaining them as an essential element in the complex, are comparatively rare.

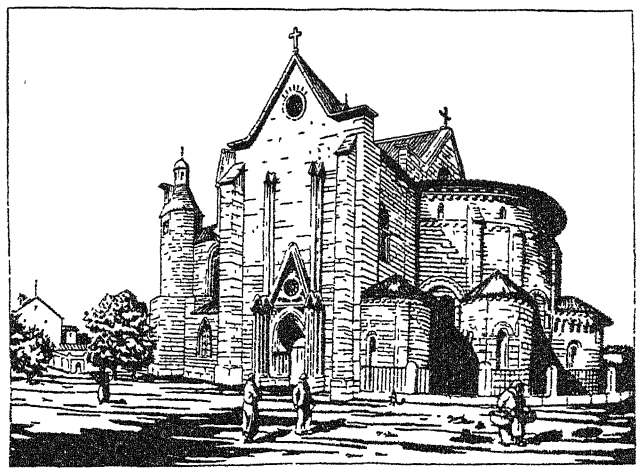
Many of the institutions which are reported from different parts of the world, though analogous to age grades, differ in one or more essential factors and are therefore to be excluded from this survey. Such institutions are found in Australia, New Guinea, in the Banks Islands, among some of the Naga tribes of Assam, and in certain American Indian societies. The *aluzhi* of the Sema Naga, for instance, are working gangs, with few sociological obligations on the members. They are bisexual, coevality is not essential, and members can be ejected from the group. When clan feeling runs high in a community the *aluzhi* groups break up, indicating that the lateral stratification of society has not the same validity as the vertical. In short, all the essentials of an age grade are lacking. The Kimta of Bartle Bay, though it has a superficial resemblance to an age grade, admits of individual members being degraded or promoted to lower or higher degrees, thus invalidating the paramount theory of group-solidarity. Again, though age is the theoretical basis of Banks Islands' societies it is in fact an unimportant factor, and at every stage of initiation except perhaps the lowest, increasingly prohibitive admission fees have resulted in "a commensality of varying years and vastly different social prospects." This is no less true of America and even in the military societies of the Hidatsa, which approach nearest to the definition, the bases of membership are purchase and age, and group-promotion is not automatic but depends on purchase.

Only in Africa, and within a limited area, is the true age grade system found functioning as a sociological element in tribal life and of the utmost importance. Nowhere do we find age grades and secret societies concurrently, for secret societies are associated with the evolution of monarchies and powerful aristocracies, which they both limit and reinforce, whereas age grades are democratic and are incompatible with any system of centralized and individual authority. This accounts for the absence of age grades in Bantu societies generally, with the exception of a few Bantu tribes of the eastern group, such as the Akikuyu, Akamba, Giriyama and Chaga, who have been considerably influenced by neighbouring Hamites and have a culture which is no longer characteristically Bantu. Similarly, on the west coast of Africa we find a system analogous to age grades among the Kru, where secret societies are almost negligible and are subordinate to the Sedibo class of age grades, which comprises the tribal legislature and executive.

The age grade is the distinctive feature of Hamitic culture and is found in all the tribes of East Africa which belong to the Hamitic or Nilo-Hamitic groups, including the Nilotic Lango. The Galla, with their very complex system, are the centre and source of this culture, and from them it has permeated all the Nilo-Hamitic tribes which cluster round them, the Masai and the Nandi, the Topotha, the Turkana and the Didinga.

There are naturally modifications and variations in the system adapted to the cultural requirements of each tribe, but the essentials are basically the same. At the puberty rites (which recur at regular intervals) a group of boys is initiated and they are thus aggregated into tribal, as opposed to family and clan, life. Henceforth they are no longer classed with the women but find themselves in a group of coevals, with a variety of lifelong privileges and obligations towards each other. Hospitality within the age group is compulsory, and at a later stage, when the members are permitted to marry, this often includes access to the wives of age-mates. The group on the formal side is distinguished by a variety of emblems, such as shield designs, bodily markings and ornaments, and a special name assumed jointly and individually at initiation by every member of the group and retained throughout life. Promotion to higher degrees of the system is automatic after a given number of years, and each degree has its own special functions, appropriate ceremonials and emblems, and often a particular diet and distinctive tabus; the warrior degree, for instance, being generally prohibited smoking, beer and marriage. The final degree usually enables the group-members to retire from the active life of the tribe to the more passive rôle of an elder.

The essence of the system is the corporate unity of the group, which moves from degree to degree as a single entity. This unity



makes the group so significant an element in tribal culture. At the puberty schools and at subsequent initiations on promotion to higher degrees the age groups receive a systematic education which, as among the Galla, may extend over 32 years. Candidates are instructed in the duties of citizenship, in tribal history and tradition, ethics, the law, hunting, war, religion, husbandry, medicine, sex, in short in every aspect of individual and communal life. They are [illegible] by hardships and privations and trained to endure all manner of physical discomforts and dangers, in order to be the better able to perform the rôle traditionally allotted to the group at each degree in its initiation. Among the Galla the system provides for the government of the country by each group in turn during its last eight years of active existence. The Masai and the majority of kindred tribes use the system for military and governmental purposes, and the Lango thanks to a changed environment, have endowed their age grade system with functions which are almost exclusively religious. Finally, the system as a whole makes for greater tribal unity by cutting across the narrow limits of the family and the clan, by giving every individual an interest in tribal, rather than parochial, concerns, and by making every individual feel that with his group he is for the time the repository of tradition and the custodian of his tribe, both heir to the past and the pledge of posterity.

**AGELADAS** or (as the name is spelled in an inscription) HAGELAIDAS, a great Argive sculptor who flourished in the latter part of the 6th and the early part of the 5th century B.C. Ageladas was said to have been the teacher of Myron, Pheidias, and Polycleitus; this tradition is a testimony to his wide fame, though historically doubtful.

**AGEMA,** the name of the bodyguard of Alexander of Macedon. It was drawn from the distinguished corps of "shield bearers" or esquires (ὑπασπισταί). While in Bactria, Alexander reorganized the agema and included some Persians.

**AGEN,** south-west France, capital of the department of Lot-et-Garonne, 84 mi. S.E. of Bordeaux by the Southern railway.

THE CATHEDRAL OF ST. CAPRAIS, AGEN, DATING FROM THE 12TH CENTURY, IS MODERN COMPARED WITH THE TOWN ITSELF WHICH WAS A CELTIC STRONGHOLD AND CONSIDERED OLD IN ROMAN TIMES

Pop. (1946) 33,397. It is skirted on the west by the Garonne, here crossed by a stone bridge and by a canal-bridge.

Agen (*Aginnum*) was the capital of the Nitiobroges, and extensive Roman ruins have been discovered. Later it was the capital of the Agenais. Its bishopric was founded in the 4th century. Agen frequently changed hands during the Albigensian wars, and at their close a tribunal of inquisition was established here. In the religious wars of the 16th century Agen took the Catholic side and joined the League in 1589. The cathedral of St. Caprais has an apse of the 12th century and three [illegible]: the rest dates from the 12th–16th centuries, the tow[illegible] the south façade is modern. The church of the Jacobins is a 13th century brick building. The prefecture (18th century) was once the bishop's palace. The *hôtel de ville* occupies the former *Hôtel du Presidial,* an obsolete tribunal, and contains the municipal library. Two houses of the 16th century, the *Hôtel d'Estrades* and the *Hôtel de Vaurs,* are used as the museum. Through its excellent water communication, Agen affords an outlet for the agricultural produce of a rich district, and forms an *entrepôt* between Bordeaux and Toulouse, dealing in poultry, prunes (*pruneaux d'Agen*), and other fruit, wine, vegetables and cattle. Flour, dried plums, *pâté de foie gras* and other delicacies, manures, drugs, woven goods and tiles are made. Agen is the seat of a bishop. It has a court of appeal and a court of assizes, tribunals of first instance and of commerce and a chamber of commerce.

**AGENAIS** or AGENOIS, a former province of France, of which Agen was the centre and to which the modern department of Lot-et-Garonne nearly corresponds. In ancient Gaul it was the country of the Nitiobriges, then a Gallo-Roman *civitas* (the 4th-century *Civitas Agennensium*) whose limits became those of the diocese of Agen. Having in general shared the fortunes of Aquitaine during the Merovingian and Carolingian periods, Agenais next became an hereditary countship; but from the middle of the 10th century it was part of the demesne of the counts of Bordeaux, dukes of Gascony; consequently in 1032 it fell to the counts of Poitiers when they inherited Gascony. The marriage of Eleanor of Aquitaine with Henry Plantagenet in 1152 brought it under England; but when Richard I married his sister Joan to Raymund VI, count of Toulouse, in 1196 Agenais formed part of her dowry, although remaining in the vassalage of Gascony. In 1249, with the other estates of Raymund VII, it lapsed to Alphonse of Poitiers, his son-in-law and the brother of Louis IX; but in 1259, by the treaty of Paris, Louis IX promised that if Alphonse and his wife Jeanne died childless their demesnes in Agenais would return to the king of England. When Jeanne did die childless in 1271, Philip III had the country occupied; but Edward I protested and it was restored to England by the treaty of Amiens in 1279. Yet the king of France claimed direct overlordship on a number of places, and the dispute over one of them (Saint-Sardos) brought a renewal of the war between France and England under Charles IV. During the Hundred Years' War Agenais was several times taken and retaken, until the final retreat of the English in 1441 left it under the French. It was for a time an appanage of Louis XI's brother Charles of Berry (1469–1472) and of Margaret of Valois (first wife of Henry IV), on whose death in 1615 it was reunited to the crown. Thenceforth Agenais was no more than an administration term. At the end of the *ancien régime* Agenais was a *sénéchaussée,* incorporated in the *gouvernement* of Guienne and the *intendance* of Bordeaux. Since the late middle ages at least, Agenais has been a rich agricultural country, subject however to alternating phases of depopulation and immigration.

**AGENT:** *see* PRINCIPAL AND AGENT.

**AGENT-GENERAL,** the term given to the representatives in England of certain of the self-governing British colonies. They are appointed, and their expenses and salaries provided, by the governments of the colonies they represent. Their duties are to look after the political and economic interests of their colonies in London, to assist in all financial and commercial matters in which their colonies may be concerned, and to make known the products of their colonies. Those colonies which are not under responsible government are represented in London by crown agents.

**AGENTS IN BUSINESS.** An agent in the most general sense is any person who transacts business for another without being a direct employee, and in the majority of cases his function is to assist a principal in the purchase, sale or distribution of goods for a remuneration which usually takes the form of

a commission on the price obtained It is a term very loosely applied. Assistance may be rendered to principals irrespective of the commercial undertakings in which they are engaged Consignment agents and credit inquiry agents are examples of this category as compared with factors or brokers who operate continuously for principals in particular industries and with manufacturers' agents who are more particularly associated with special lines of goods There is an intermediate class of agents not directly concerned with the sale of goods and therefore not remunerated on a commission basis but who are of vital importance to the producer and manufacturer, the two most important being (*a*) advertising agents, whose function is to promote the commercial activity which is the beginning and the end of every undertaking, and (*b*) patent agents whose services are needed in most cases before manufacture can be commenced and who are also in a position to introduce their clients to the agents best qualified to market the product.

**Manufacturers' Agents.**—In the early stages of a manufacturing business when problems of production absorb the energies of the proprietor he is frequently glad to be relieved of all marketing problems by handing over the entire output to be disposed of by one or more manufacturers' agents on the commission basis which maintains this important section of the trading community The method usually adopted is to sell by sample, the principal making arrangements for delivery and collecting accounts. But some manufacturers' agents operate on a much larger scale, especially in the textile industry, maintaining warehouses, stock rooms and administrative departments. The intimate knowledge possessed by the manufacturers' agent of the various requirements of the public is of great value to the principal; so much is this the case that the advisory services of the agent may be vital to the success of the undertaking and his influence on the policy of the business as powerful as if he were a partner. An agent of this standing is invariably consulted before new lines are introduced and he periodically brings forward suggestions calculated to increase trade which will bring him increased commission and the principal increased turnover.

**Factors.**—The tendency of modern business is to shorten the chain between producer and consumer, the chief forces operating being the extension of advertising in all directions, the growth of consumer co-operation and the increase in competition which leads to producer co-operation and the formation of trusts or buying groups. The effect on the manufacturers' agent is for him to accept greater personal responsibilities and virtually to take over the functions of a factor who, while his remuneration is also on a commission basis, is much more independent of his principal than is the manufacturers' agent. Invariably the factor has possession of the goods of the principal; he is generally able to get a better price and sells the goods as though they were his own, leaving the buyer no clue to identity. He also frequently acts as banker for his principal, owing to the necessity of his carrying a large stock for disposal in anticipation of increased demand. It is in his interests to induce the manufacturer to produce on a larger scale at a lower cost than if the production were small, and this is done by his relieving the manufacturer of the necessity of recouping the expenditure of production with a quick sale. The factor is a large-scale operator in a number of industries, produce, textile, grain, hide, etc., and like the manufacturers' agent is continually exposed to the pressure of the forces making for a shorter chain between producer and consumer. The tendency is for him to discharge other marketing functions, to buy manufacturing businesses and do the work of a wholesale merchant.

**Brokers.**—A broker is an intermediary whose function is simply to buy or sell on behalf of a client, and who does not have possession of the goods dealt with. He is present at all exchanges where produce is disposed of and business arranged. He has a specialized knowledge of particular classes of goods, their sources of supply and the avenues of marketing. His duties are of a personal character, only a small establishment being required as his business is carried on by negotiation at the exchange and in the offices of clients. In the produce market brokers are indispensable—they study the crop reports, watch cargoes, take samples, collect statistics and furnish market reports. Pressure of competition and the shortening of the producer-consumer chain impels the broker to buy and sell on his own account.

(*See* ADVERTISING AGENT; BROKER.) (A. B. C.)

**AGENTS OF PRODUCTION**, in economics, a term used to describe the factors which combine in the production of wealth, as land, labour (*qq.v.*), capital and organization. (*See* AGRICULTURAL ECONOMICS; CAPITAL AND INTEREST; ECONOMICS; ENTREPRENEUR.)

**AGESANDER**, a Rhodian sculptor who is mentioned by Pliny (*Nat. Hist.*, xxxvi, 37) as author (with Polydorus and Athenodorus) of the group of the Laocoön Inscriptions found at Lindus in Rhodes date Agesander and Athenodorus to the period 42–21 B.C.

**AGESILAUS II,** king of Sparta, of the Eurypontid family, was the son of Archidamus II and Eupolia, and the younger stepbrother of Agis, whom he succeeded about 401 B.C. Agis had, indeed, a son Leotychides, but he was set aside as illegitimate, current rumour representing him as the son of Alcibiades. Agesilaus' success was largely caused by Lysander, who hoped to find in him a willing tool for the furtherance of his political designs. In this hope, however, he was disappointed, and the increasing power of Agesilaus soon led to Lysander's downfall In 396 Agesilaus was sent to Asia with a force of 2,000 neodamodes (enfranchised helots) and 6,000 allies to secure the Greek cities against a Persian attack. On the eve of sailing from Aulis he attempted to offer a sacrifice, as Agamemnon had done before the Trojan expedition, but the Thebans intervened to prevent it, an insult for which he never forgave them. On his arrival at Ephesus a three-months' truce was concluded with Tissaphernes, the satrap of Lydia and Caria, but negotiations conducted during that time proved fruitless, and on its termination Agesilaus raided Phrygia, where he easily won immense booty since Tissaphernes had concentrated his troops in Caria. After spending the winter in organizing a cavalry force, he made a successful incursion into Lydia in the spring of 395. Tithraustes was thereupon sent to replace Tissaphernes, who paid with his life for his continued failure

An armistice was concluded between Tithraustes and Agesilaus, who left the southern satrapy and again invaded Phrygia, which he ravaged until the following spring.

He then came to an agreement with the satrap Pharnabazus and once more turned southward. It was said that he was planning a campaign in the interior, or even an attack on Artaxerxes himself, when he was recalled to Greece because of the war between Sparta and the combined forces of Athens, Thebes, Corinth, Argos and several minor states. A rapid march through Thrace and Macedonia brought him to Thessaly, where he repulsed the Thessalian cavalry which tried to impede him. Reinforced by Phocian and Orchomenian troops and a Spartan army, he met the confederate forces at Coronea in Boeotia, and in a hotly contested battle was technically victorious, but the success was a barren one and he had to retire by way of Delphi to the Peloponnese. Shortly before this battle the Spartan navy, of which he had received the supreme command, was totally defeated off Cnidus by a powerful Persian fleet under Conon and Pharnabazus.

Agesilaus took a leading part in the Corinthian War, making successful expeditions into Corinthian territory, and capturing Lechaeum. But the destruction of a *mora* by Iphicrates neutralized these successes, and Agesilaus returned to Sparta. In 387 the Peace of Antalcidas (*q.v.*), which was warmly supported by Agesilaus, put an end to hostilities. When war broke out afresh with Thebes the king twice invaded Boeotia (378, 377) and it was on his advice that Cleombrotus marched against Thebes in 371. Cleombrotus was defeated at Leuctra and the Spartan supremacy overthrown. In 370 Agesilaus tried to restore Spartan prestige by invading Mantinean territory and his heroism saved Sparta when Epaminondas penetrated Laconia that same year, and again in 362 when he all but succeeded in seizing the city. Sparta stood aloof from the general peace of 362 hoping to recover its supremacy. In order to gain money for the war Agesilaus had supported the revolted satraps; in 361 he went to Egypt at the head of a mercenary force to aid Tachos against

Persia, and died, at the age of 84, on his way home.

Agesilaus was a small man, somewhat lame from birth. He was a successful leader in guerilla warfare, alert and quick, yet cautious, and his bravery was unquestioned. He lived in the most frugal style and enriched the state and his friends with the spoils of his campaigns, returning himself as poor as he had set forth He was sincerely patriotic, but the worst trait in his character was his implacable hatred of Thebes, which led to the battle of Leuctra and Sparta's fall from supremacy

**AGGLOMERATE,** the term applied to coarse fragmental rocks produced by explosive volcanic eruptions, and consisting mainly of rounded or subangular bombs, at least partly plastic when erupted, that lie in a matrix of tuff and are found within or near volcanic pipes. Volcanic breccias differ from agglomerates in the angularity of the fragments, which are erupted in a solid condition. (H. Ws.)

**AGGLUTINATION,** a term used technically in philology for the method of word formation by which two significant words or roots are joined together in a single word to express a combination of the two meanings each of which retains its force (Lat *ad* and *glutinare,* lit. to fasten together with glue) This juxtaposition or conjoining of roots is characteristic of languages such as the Turkish and Japanese, which are therefore known as agglutinative, as opposed to others, known generically as inflexional, in which differences of termination or combinations in which all separate identity disappears are predominant.

The term was also formerly used by associationist philosophers for those mental associations which were regarded as peculiarly close. W. Wundt applies this term to those simplest cases of apperceptive synthesis in which the simpler ideas composing the complex idea retain their independence—as, for instance, in the idea expressed by "church-steeple." (X.)

In medicine, the holding together of wound edges as a part of the process of early healing is called agglutination, as is the clumping of bacteria, organisms or cells in some fluid medium either natural or artificial. It is believed to be caused by more or less specific substances called agglutinins. The reaction may be seen under a microscope or with the naked eye in some cases. This phenomenon is utilized to determine the existence of a disease such as typhoid fever and also to decide whether or not a specific blood is a safe one for transfusion. (F L. A.)

**AGGRAVATION** (Lat. *ad,* "increasing," *gravis,* "heavy"), the making anything graver or more serious; also used as synonymous with "irritation." In the canon law "aggravation" was a form of ecclesiastical censure, threatening excommunication after three disregarded admonitions.

**AGGREGATE,** a term used in building and construction to designate the material with which cement, lime, gypsum or other adhesive material, such as bitumen, is mixed to form a concrete or mortar (*q.v.*). The most common aggregates are sand, crushed or broken stone, gravel or pebbles, broken blast-furnace slag, boiler ashes or clinker, burned shale and burned clay. The purpose of the aggregate is to provide volume, freedom from change in volume, and resistance to wear or erosion and other desired physical properties, in the finished product.

Aggregates are divided into two general classes commonly known as fine aggregate and coarse aggregate. The fine aggregate is generally sand, crushed stone or crushed slag screenings; the coarse aggregate is gravel (pebbles), fragments of broken stone, slag and the other substances above mentioned. The dividing line between fine and coarse aggregate is usually a ¼-in. screen opening, sometimes a ⅛-in. opening. Aggregates are mixed with the cement or binding material in proportions varying from one part of cementing material to one part of fine aggregate for a "rich" mortar to one part of cement to nine or ten parts of mixed fine and coarse aggregates for a "lean" concrete. The theory upon which such mixtures are proportioned is that there shall be sufficient cementing material to coat all of the particles in the fine aggregate, and that there shall be sufficient mortar so produced to fill all the voids in the coarse aggregate. The ideal concrete would consist of closely packed fragments of crushed stone, slag or pebbles in which all the fragments are coated with mortar, and all the voids between the coarser fragments filled with mortar. Under actual conditions in construction work there is practically always an excess of mortar Nearly all natural sands require washing or rinsing to remove loam, clay, organic material, etc. A gradual variation in size from about 50 mesh (50 openings per linear inch) to ¼-in. mesh is desirable for the strongest mortar or concrete The preparation of commercial fine aggregate therefore often requires artificial grading or mixing of the various sizes. This is usually accomplished by hydraulic separation of the undesirable fine sizes, which usually are in excess. For coarse aggregate any hard, tough, durable rock may be crushed, screened and graded The common commercial sizes vary from ¼ in to 3½ in. in largest dimension The most desirable rocks for general construction purposes are basalt, commonly called trap, and fairly pure limestone. Such rocks are not only durable but fire-resisting. Specification requirements include cleanliness (maximum limits of extraneous impurities), limiting percentages of various sizes, soundness (freezing and thawing tests, for example), sometimes mineralogical composition (designed to ensure soundness).

In this age of concrete construction and road building the business of supplying aggregates for construction work has grown to large proportions. In the U S. alone production amounts to approximately 300,000,000 tons per annum, valued roughly at $300,000,000, requiring an investment of about $500,000,000 in washing, screening and crushing equipment and accessory machinery for mining and conveying the raw and finished materials.

**AGGREGATES, THEORY OF.** An aggregate may be defined as a collection of objects of some kind or other. In mathematics the objects making up an aggregate are usually mental objects; *i.e.,* concepts or ideas. However, material objects may also be used to constitute an aggregate. Other synonyms for aggregate are: class, set, domain, totality. In this article these words will be used interchangeably. Writers on mathematics sometimes make special distinctions between them for special purposes.

The theory of aggregates was developed enthusiastically by Georg Cantor and other mathematicians in the latter part of the 19th century, but the uncritical use of its concepts and methods soon led to logical contradictions. Workers in mathematical logic made a variety of attempts to set up rules which would prevent these contradictions, but no general agreement as to a desirable method was reached. However, contradictions are not met in the uses to which the theory of classes is actually put in mathematics.

**Determination of an Aggregate.**—The fundamental relation in the theory of classes is that of class membership. This may be taken as an undefined relation, whose meaning is understood from the way in which it is used. The symbol $x \epsilon A$ is frequently used to state that an object $x$ is a member of a class $A$. A class is well-defined when a workable criterion is given for telling what objects are members of it. Thus, a class may be determined by a suitably stated property or a suitably worded "propositional form," or in some cases by simply pointing out its members. The class of all people who have blue eyes is not well-defined for mathematical purposes, first, because it may sometimes be difficult to determine whether a person's eyes are blue or gray, and second, because people are continually being born and dying. On the other hand, the class of all integers greater than 10 and less than 100 is a mathematically well-determined class.

**Operations on Aggregates.**—A class $A$ is said to be a subset of a class $B$ in case every member of $A$ is also a member of $B$. This relation of class inclusion is indicated by the notation $A \subset B$, which is read "$A$ is a subset of $B$," "$A$ is included in $B$," or "$A$ is contained in $B$." Let $U$ denote a fixed class, and denote sub-

classes of $U$ by the letters, $A, B, C, \ldots$. The fundamental operations on classes are: logical addition, logical multiplication and logical subtraction. The sum $A+B$ of two classes (also called the union of $A$ and $B$) is the class consisting of all the members of $A$ or $B$ or both. The product $AB$ of two classes (also called the intersection of $A$ and $B$) is the class consisting of all the objects which are simultaneously members of both $A$ and $B$. The difference $A-B$ consists of all the objects which are members of $A$ but not members of $B$. The special difference $U-B$ is called the complement of $B$, and denoted by $cB$. The operations of logical addition and logical multiplication may clearly be applied to any number of classes and even to an infinite collection of classes. In order that the operations of logical multiplication and logical subtraction may always be carried out, a special class, called the null class, and having no members, is introduced by agreement. If $A \subset B$, then $A-B$ is the null class. The null class behaves with respect to logical addition and multiplication much as 0 does in ordinary algebra. Logical addition and multiplication obey the associative, commutative and distributive laws of ordinary algebra, and also the new distributive law: $A+BC=(A+B)(A+C)$. But logical subtraction does not behave like ordinary subtraction, since $(A+B)-C$ is not always equal to $A+(B-C)$. Also $(A-B)(A-C)=A-(B+C)$. Another important operation on two classes $A$ and $B$ is the Cartesian product $A \times B$, which is defined as the aggregate of all pairs $(x, y)$ of which the first element $x$ is a member of $A$, and the second element $y$ is a member of $B$. This kind of product is named after the French mathematician René Descartes. In his analytic geometry the points of a plane are represented by pairs of numbers $(x, y)$, where the numbers $x$ and $y$ represent distances measured respectively along two intersecting lines in the plane. The Cartesian product is not commutative, but it is distributive with respect to logical addition, and also with respect to logical multiplication, that is, $(A+B)\times C=(A\times C)+(B\times C)$, $(AB)\times C=(A\times C)(B\times C)$.

**Finite and Infinite Aggregates.**—An important distinction is that between finite and infinite aggregates. This distinction is defined logically, by means of the notion of one-to-one correspondence. An aggregate $A$ is said to be in one-to-one correspondence with an aggregate $B$ when each element $a$ of $A$ is paired with one and only one element $b$ of $B$, and vice versa. If for every possible one-to-one correspondence between $A$ and a subset $B$ of $A$ it is true that $B$ is the whole of $A$, then $A$ is said to be finite. But if there is a one-to-one correspondence between $A$ and a proper part $B$ of $A$, then $A$ is said to be infinite. The size of aggregates is compared by means of this notion of one-to-one correspondence, and this leads to the notion of number (*q.v.*). The numbers associated with infinite classes by means of this notion of one-to-one correspondence are called transfinite cardinal numbers. (*See* also INFINITY AND THE INFINITE.) The numbers associated with finite classes are called natural numbers. If an aggregate $A$ can be put into one-to-one correspondence with the set of all the natural numbers, it is said to be countably infinite. The cardinal number of countably infinite aggregates is usually denoted by $\aleph_0$. It is the smallest infinite cardinal.

**Theory of Aggregates in Mathematics.**—The theory of aggregates is fundamental for all of mathematics. Many of the branches of mathematics are characterized to some extent by the special structure or properties assumed for the aggregates considered in them. For example, part of algebra is concerned with aggregates whose elements are numbers, and with the operations of addition, multiplication, etc., performed on those elements. Geometry is concerned with aggregates whose elements may be called points, and with operations of motion, projection, deformation, etc., and relations of congruence, distance, etc. Aggregates in geometry are frequently called point sets. (*See* TOPOLOGY; POINT SETS.)

One of the basic notions in mathematics is that of ordered aggregates. A class $A$ is said to be ordered if a relation of precedence is set up between pairs of elements of $A$, with the following properties: (1) if $x$ and $y$ are distinct elements of $A$, then $x<y$ (read "$x$ precedes $y$") or $y<x$; (2) if $x<y$ and $y<z$ then $x<z$; (3) no two of $x=y$, $x<y$, $y<x$ can hold simultaneously. In case the ordering in $A$ is such that every subclass $B$ of $A$ has a first element $x_0$, that is, $x_0$ precedes every other element of $B$, then $A$ is said to be well-ordered. Every ordering of a finite class is a well-ordering but this is no longer true for infinite classes. For example, the natural numbers in their usual order form a well-ordered class, but if the order is reversed it is no longer a well-ordering of the class.

**AGGREGATION,** in physics, a collective term for the forms or states in which matter exists. Three primary "states of aggregation" are recognized—gaseous, liquid and solid. Generally, if a solid is heated to a certain temperature, it melts or fuses, assuming the liquid condition (*see* FUSION); if the heating is continued the liquid boils and becomes a vapour (*see* VAPORIZATION). On the other hand, if a gas is sufficiently cooled and compressed, it liquefies; this transition is treated theoretically in the article LIQUEFACTION OF GASES.

**AGGTELEK,** a village in northern Hungary in that portion of the county of Gömör that remained in 1918 within Hungarian rule. Although small (pop. 648), it is world-renowned for its remarkable limestone grotto, the Aggtelek or Baradla cavern, one of the largest of its kind in Europe. It is composed of a labyrinth of passages and halls of various sizes, the total length, including its ramifications, exceeding 5 mi. A stream traverses the caves, which are rich in fantastic stalactite forms.

**AGINCOURT** (AZINCOURT), a village of northern France in the department of Pas de Calais, 14 mi. N.W. of St. Pol by road, famous on account of the victory, on Oct. 25, 1415, of Henry V of England over the French. The battle was fought in the defile formed by the wood of Agincourt and that of Tramecourt, at the northern exit of which the army under Charles d'Albret, constable of France, had placed itself so as to bar the way against the English forces which, after the capture of Harfleur, had set out to march through Picardy to Calais. Torrential rains hindered the English in crossing the Somme, and the delay allowed the French to concentrate in overwhelming numbers—d'Albret, indeed, refused to avail himself of the offer of 6,000 crossbowmen of the Paris citizen militia. Worse still, the English became so short of supplies that had the French but been content to block the path without risking an attack, hunger would have brought them the victory. The night of Oct. 24 was spent by the two armies on the ground, and the English had but little shelter from the heavy rain. Early on the 25th, St. Crispin's day, Henry arrayed his little army (about 1,000 men-at-arms, 6,000 archers, and a few thousands of other foot). It is probable that the usual three "battles" were drawn up in line, each with its archers on the flanks and the dismounted men-at-arms in the centre; the archers being thrown forward in wedge-shaped salients, almost exactly as at Crécy (*q.v.*). The French, on the other hand, were drawn up in three lines, each line formed in deep masses. They were at least four times more numerous than the English, but restricted by the nature of the ground to the same narrow front 1,100 yd., they were unable to use their full weight (*cf.* Bannockburn); further, the deep mud prevented their artillery from taking part, and the crossbowmen were as usual relegated to the rear of the knights and men-at-arms. All were dismounted save a few knights and men-at-arms on the flanks, who were intended to charge the archers of the enemy. For three hours after sunrise there was no fighting; then Henry, finding that the French would not advance, moved his army farther into the defile. The archers fixed the pointed stakes, which they carried to ward off cavalry charges, and opened the engagement with flights of arrows. The chivalry of France, undisciplined and too obtuse to have assimilated the lesson of Crécy and Poitiers, was quickly stung into action, and the French mounted men charged, but their slow-moving horses made easy targets, soon shot down or driven back in confusion. The constable himself headed the leading line of dismounted men-at-arms; weighted with their armour, and sinking deep into the mud with every step, they yet reached and

engaged the English men-at-arms; for a time the fighting was severe. The thin line of the defenders was borne back and King Henry was almost beaten to the ground But at this moment the archers, taking their hatchets, swords or other weapons, penetrated the gaps in the now disordered French, who could not move to cope with their unarmoured assailants, and were slaughtered or taken prisoners to a man. The second line of the French came on, only to be engulfed in the *mêlée;* its leaders, like those of the first line, were killed or taken, and the commanders of the third sought and found their death in the battle, while their men rode off to safety The closing scene of the battle was a half-hearted attack made by a body of fugitives, which led merely to the slaughter of the French prisoners, which was ordered by Henry because he had not enough men both to guard them and to meet the attack The slaughter ceased when the assailants drew off The total loss of the English is stated at 13 men-at-arms (including the duke of York, grandson of Edward III.) and about 100 of the foot The French lost 5,000 of noble birth killed, including the constable, three dukes, five counts and 90 barons; 1,000 more were taken prisoners, amongst them the duke of Orleans (the Charles d'Orléans of literature). The moral lesson of the battle was the incapacity of a military caste to learn from experience, and to adapt their traditions intelligently to new needs. The material lesson was that armour stultified its own purpose when it fettered mobility The 15th-century soldier pinned his faith as obstinately on an increasing weight of armour as the 19th-century soldier on an increasing weight of numbers

**AGIO,** a term used in commerce in three connections.

(a) The variations from fixed pars or rates of exchange in the currencies of different countries For example, in most of the gold-standard countries, the standard coin is kept up to a uniform point of fineness, and so bears a constant relation to coins of other countries in a similar condition. This is what is known as the mint par of exchange. The balance of trade between the various countries is the factor determining the rate of exchange Should the balance of trade be against England, money must be remitted to France as payment for the indebtedness. But owing to the cost for the transmission of specie there will be a demand for bills as a cheaper and more expeditious method of sending money, and it therefore will be necessary to pay a premium for it, called the agio.

(b) The term is also used to denote the difference in exchange between two currencies in the same country; where silver coinage is the legal tender, agio is sometimes allowed for payment in the more convenient form of gold, or where the paper currency of a country is reduced below the bullion which it professes to represent, an agio is payable on the appreciated currency.

(c) Lastly, in some states the coinage is so debased, owing to the wear of circulation, that the real is greatly reduced below the nominal value. Supposing that this reduction amounts to 5%, then if 100 sovereigns were offered as payment of a debt in England while such sovereigns were current there at their nominal value, they would be received as just payment; but if they were offered as payment of the same amount of debt in a foreign state, they would be received only at their intrinsic value of £95, the additional £5 constituting the agio. Where the state keeps its coinage up to a standard value no agio is required. (*See* BALANCE OF TRADE.)

**AGIRA** (formerly San Filippo d'Argirò), town in the province of Enna, Sicily, with a railway station 4½ mi. to the south; 35 mi. W. of Catania. Pop. (1901) 17,738; (1936) 14,411 (town), 15,350 (commune). *Agyrion,* an ancient Sicel city, was ruled by tyrants, one of whom, Agyris, was contemporary of Dionysius I., and with him successfully resisted the Carthaginians in 392 B.C. Agyrion was not colonized by the Greeks until Timoleon drove out the last tyrant in 339 B.C.

**AGIS,** the name of four Spartan kings:

(1) Son of Eurysthenes, founder of the royal house of the Agiadae (Pausanias iii 2. 1). His genealogy was traced back to Heracles (Herodotus vii. 204), and he belongs rather to mythology than to history. Tradition ascribed to him the capture of Helos, and the institution of the class of serfs called Helots (*q.v.*). *See* Ephorus ap Strabo, viii. p 365.

(2) AGIS I., son of Archidamus II., Eurypontid, succeeded his father, probably in 427 B.C., and from his first invasion of Attica in 425 down to the close of the Peloponnesian War was the chief leader of the Spartan operations on land After the conclusion of the peace of Nicias (421 B.C.) he marched against the Argives in defence of Epidaurus, and after skilful manoeuvring surrounded the Argive army, and seemed to have victory within his grasp when he unaccountably concluded a four months' truce and withdrew his forces The Spartans were indignant, and when the Argives and their allies broke the truce Agis escaped having his house razed and a fine of 100,000 drachmae imposed only by promising to atone for his error by a signal victory This promise he fulfilled by routing the forces of the Argive confederacy at the battle of Mantinea (418) In the winter 417–416 a further expedition to Argos resulted in the destruction of the half-finished Long Walls and the capture of Hysiae. In 413, on the suggestion of Alcibiades, he fortified Decelea in Attica, where he remained directing operations until, after the battle of Aegospotami (405), he took the leading part in the blockade of Athens, which was ended in the spring of 404 by the surrender of the city Subsequently he invaded and ravaged Elis He fell ill on his return from Delphi, where he had gone to dedicate a tithe of the spoils, and died at Sparta, probably in 401.

Anim.* 6. (*See* PELOPONNESIAN WAR.)

(3) AGIS II., son of Archidamus III., of the Eurypontid line. succeeded his father in 338 B.C., on the very day of the battle of Chaeronea. During Alexander's Asiatic campaign he revolted against Macedonia (333 B.C.) and, with the aid of Persian money and ships and a force of 8,000 Greek mercenaries, gained considerable successes in Crete. In the Peloponnese he routed a force under Corragus and, although Athens held aloof, he was joined by Elis, Achaea (except Pellene) and Arcadia, with the exception of Megalopolis, which the allies besieged. Antipater marched rapidly to its relief at the head of a large army, and the allied force was defeated after a desperate struggle (331) and Agis was slain.

BIBLIOGRAPHY.—*See* Pausanias iii. 10 5; Diodorus xvii. 48, 62, 63; Justin xii. 1, Quintus Curtius iv., 1, 39, vi., 1; Arrian, *Anabasis,* ii. 13.

(4) AGIS III., son of Eudamidas II., of the Eurypontid family, succeeded his father, probably in 245 B.C., in his 20th year at a time when the unequal distribution of land and wealth and the diminution in the number of full citizens threatened to ruin Sparta. He determined to restore the traditional institutions of Lycurgus. Lysander as ephor proposed on behalf of Agis that all debts should be cancelled and that Laconia should be divided into 19,500 lots, of which 4,500 should be given to Spartiates, whose number was to be recruited from the best of the perioeci and foreigners, and the remaining 15,000 to perioeci who could bear arms The abolition of debts was carried into effect, but the land distribution was put off on various pretexts by Agesilaus, the king's uncle, who wished to preserve his estates. At this point Aratus appealed to Sparta to help the Achaeans in repelling an expected Aetolian attack, and Agis was sent to the Isthmus at the head of an army. During his absence his enemies gained the upper hand, and on his return Agis, after a mock trial, was strangled in prison, his mother and grandmother sharing the same fate (241).

*See* Plutarch's biography. Pausanias' accounts (ii. 8. 5, vii. 7. 3, viii. 10. 5-8, 27. 13) of his attack on Megalopolis, his seizure of Pellene and his death at Mantinea fighting against the Arcadians. Achaeans and Sicyonians are without foundation (J. C. F. Manso. *Sparta.* iii. 2. 123–127, 1800–05). *See* also Manso, *op. cit* iii. 1. 276–302; B. Niese, *Geschichte der griechischen und makedonischen Staaten,* ii. 299–303 (1884).

**AGISTMENT.** To "agist" is, in law, to take cattle to graze, for a remuneration. The word is derived through O. Fr. from Lat. *iacere,* to lie. "Agistment," in the first instance, referred

more particularly to the proceeds of pasturage in the king's forests, but now means either (*a*) the contract for taking in and feeding horses or other cattle on pasture-land, for the consideration of a weekly payment of money, or (*b*) the profit derived from such pasturing. Agistment is a contract of bailment, and the bailee is bound to take reasonable care of the animals entrusted to him; he is responsible for damages and injury which result from ordinary casualties, if it be proved that such might have been prevented by the exercise of reasonable care.

There is no lien on the cattle for the price of the agistment, unless by express agreement. Under the Agricultural Holdings Act, 1883, agisted cattle cannot be distrained on for rent if there be other sufficient distress to be found, and if such other distress be not found, and the cattle be distrained, the owner may redeem them on paying the price of their agistment.

**AGITATION, THERMAL,** the motion of the molecules, within a body, which they possess by virtue of their absolute temperature. (*See* KINETIC THEORY OF MATTER; THERMODYNAMICS.)

**AGITATO** (Ital.), a musical term implying that the composition or passage so marked is to be played in a restless, agitated manner, a rapid *tempo* being usually indicated at the same time by the accompanying time-direction, *e.g*, *presto agitato.*

**AGITATORS** or ADJUTATORS, the name given to representatives elected in 1647 by the different regiments of the English parliamentary army. Early in 1647 the Long Parliament wished either to disband many of the regiments or to send them to Ireland. The soldiers, whose pay was largely in arrear, refused to accept either alternative, and eight of the cavalry regiments elected agitators, called at first commissioners, who laid their grievances before the three generals, and whose letter was read in the House of Commons on April 30, 1647. The other regiments followed the example of the cavalry, and after a temporary conciliation Parliament decided to disband the army on June 1. The agitators determined to resist; a mutiny occurred in one regiment and the attempt at disbandment collapsed. There followed the seizure of the king by Cornet Joyce, Cromwell's definite adherence to the policy of the army, the signing of the manifestos, a *Humble Representation* and a *Solemn Engagement,* and the establishment of the army council composed of officers and agitators. The agitators finally demanded a march towards London and the "purging" of the House of Commons. Subsequent events are part of the general history of England. Gradually the agitators ceased to exist, but many of their ideas were adopted by the Levellers (*q.v.*), who may perhaps be regarded as their successors.

*See* S. R. Gardiner, *History of the Great Civil War,* vols. iii. and iv. (1905).

**AGNANO, LAGO DI,** a crater lake, 5 m. W. of Naples, Italy; 4 m. in circumference, not mentioned in antiquity, probably formed in the Middle Ages, drained in 1866. It has a large modern thermal establishment with springs, natural sulphurous vapour baths and a grotto with constant exudation of warm carbonic-acid gas from the floor. There are extensive Roman remains (V. Macchioro, *Monumenti dei Lincei,* xxi. p. 225. *sqq.*, 1911). On the north side of the crater is a racecourse.

**AGNATES,** in Roman law, persons related through males only, as opposed to cognates. Agnation was founded on the idea of the family held together by the *patria potestas; cognatio* involves simply the modern idea of kindred.

**AGNES, SAINT,** a virgin martyr of the Catholic Church. The legend of St. Agnes is that she was a Roman maid, by birth a Christian, who suffered martyrdom at the age of 13, during the reign of the emperor Diocletian, on Jan 21, 304. The prefect Sempronius wished her to marry his son, and on her refusal condemned her to be outraged before her execution, but her honour was miraculously preserved. When led out to die she was tied to a stake, but the faggots would not burn, whereupon the officer in charge of the troops drew his sword and struck off her head. St Agnes is the patron saint of young girls, who, in rural districts, formerly indulged in all sorts of quaint country magic on St. Agnes' Eve (Jan. 20–21) with a view to discovering their future husbands. This superstition has been immortalized in Keats's poem, "The Eve of St. Agnes." St. Agnes's bones are supposed to rest in the church of her name at Rome, originally built by Constantine and restored by Pope Honorius in the 7th century. Here on her [illegible] 21) two lambs are specially blessed after pontifical high mass, and their wool is later woven into pallia.

**AGNESI, MARIA GAETANA** (1718–1799), Italian mathematician, linguist and philosopher, was born at Milan on May 16, 1718. She was an extremely precocious child. Her father was a professor of mathematics. Maria was only fourteen when she began to read a series of theses on philosophical questions to the learned men of Bologna who met regularly in her father's house (*see* Brosse, *Lettres sur l'Italie*). Her family resisted her early desire to enter a convent, but from her 20th year onward she lived in complete seclusion at home, devoting herself to the study of mathematics. When her father fell ill in 1752 Pope Benedict XIV. appointed her to his chair in the university. But on his death in 1754 she became directress of the Hospice Trivulzio of the Blue Nuns at Milan, and eventually joined the sisterhood. She died on Jan. 9, 1799. Her principal work is *Instituzioni analitiche ad uso della gioventu italiana* (2 vols., Milan 1748; French trans. of vol. i., Paris 1775; complete Eng. trans by John Colson, 1801).

Her sister, MARIA TERESA AGNESI (1724–80), composed several cantatas, two pianoforte concertos and five operas.

BIBLIOGRAPHY.—*See* Antonio Francesco Frisi, *Éloge historique de Mademoiselle Agnesi,* translated by Boulard (Paris, 1807); Milesi-Mojon, *Vita di M. G. Agnesi* (Milan, 1836); J. Boyer, "La Mathématicienne Agnesi," in the *Revue Catholique des revues francaises et étrangères* (Paris, 1897).

**AGNES OF MERAN** (d. 1201), queen of France, was the daughter of Bertold IV, duke of Meran in Tirol. In June 1196 she married Philip II, king of France, who had repudiated Ingeborg of Denmark in 1193. The pope espoused the cause of Ingeborg and eventually put the kingdom under an interdict, whereupon Philip pretended to agree to a separation from Agnes. In fact, he did not turn her away, and Ingeborg was imprisoned. Agnes died in Aug. 1201. The pope legitimized her children by Philip.

**AGNEW, DAVID HAYES** (1818–1892), U.S. surgeon, was born in Lancaster county, Pa., on Nov. 24, 1818. He graduated from the University of Pennsylvania in 1838, and became a lecturer at the Philadelphia School of Anatomy. He was appointed surgeon at the Philadelphia hospital in 1854 and was the founder of its pathological museum. For 26 years (1863–89) he was connected with the medical faculty of the University of Pennsylvania.

From 1865 to 1884—except for a brief interval—Agnew was a surgeon at the Pennsylvania hospital. During the American Civil War he was consulting surgeon in the Mower Army hospital, near Philadelphia, and acquired considerable reputation for his operations in cases of gun-shot wounds. He attended as operating surgeon when Pres. James Garfield was fatally wounded by the bullet of an assassin in 1881.

Agnew was the author of several works, the most important being *The Principles and Practice of Surgery* (1878–83). He died in Philadelphia on March 22, 1892.

See *Surgery, Gynecology and Obstetrics,* pp. 295–299 (Feb. 1928).

**AGNI,** the fire god of the Hindus, second only to Indra in the Vedic mythology of India. He is invoked as "priest of sacrifice" in the first verse of the *Rig-Veda,* and, as messenger, between gods and men, sacrifices to him are upborne to the deities. On earth his parents are the two sticks of the fire drill, and every day he is reborn an immortal, living among men and supreme director of religious rites and duties. His form is however three-fold, fire on earth, lightning and the sun, and in art he is depicted as ruddy, with two faces, beneficent and malignant, three-legged (as in the fylfot. with seven arms). Later he was identified with Rūdra (*q.v.*). In modern India he has no professed sect, but is invoked in many ceremonies, and specially

affected by Agnihotri Brahmans who perform the "fire sacrifice" (*agnihotra*).

*See* A. A. Macdonell, *Vedic Mythology*, and F. Wast[illegible], *Epic Mythology* (1897 and 1915); J. N. Farquhar, [illegible] *Literature of India* and Mrs. Sinclair Stevenson, *Rites of the* [illegible] (1920).

**AGNI,** inhabitants of the Cold Coast and the French Ivory Coast between the Fanti territory and the Comoé river, south of the Abron (*q.v.*) people. They are of the same origin and have the same physical, social and linguistic characteristics as the Baule [illegible].

**AGNOETAE,** a minority of adherents to the Monophysite movement who (contrary to the general tendency of that form of Christology) maintained that Christ as man was ignorant of many things (Mark xiii. 32; Luke ii. 25) (Gr. ἀγνοέω, "be ignorant of"). The doctrine was condemned by Gregory the Great. (*See* MONOPHYSITES.)

**AGNOIOLOGY** (the theory of ignorance). The term was used by J. F. Ferrier (*Institutes of Metaphysics,* 1854) as a set-off to *Epistemology* (theory of knowledge). The theory was intended to counter the sceptical contention that Absolute Being may be beyond human knowledge, that the human mind may be condemned to remain ignorant of it. Ferrier's contention is that man cannot be said to be ignorant of what cannot be known; he can only be said to be ignorant when he does not know what can be known. On such lines Ferrier concludes that, since Absolute Being must either be something that we know or something that we are ignorant of, it cannot be subject only or object only but a synthesis of both.

**AGNOSTICISM.** Whereas scepticism, as a technical term in philosophy, denotes varying degrees of doubt as to whether some or all of the psychological processes, purporting to yield knowledge, really do so, agnosticism rather asserts that, of certain kinds of objects or facts, we possess assured knowledge, while as to certain other kinds of alleged existents we have, and can have, none. The kinds of alleged objects, knowledge as to which the agnostic believes to be impossible, are such as are the primary concern of metaphysics and theology: God, the soul and its immortality, and—more generally speaking—the ultimate realities of which phenomenal things, such as the sciences study, are appearances. Of these phenomenal things, we have ever-increasing and irrefragable knowledge; as to the things *per se,* the ontal or noumenal existents, of which the "things" of common sense and science are the knowable shadows or appearances, we can never have knowledge pure and subjectively undefiled. If we know *that* they are, we cannot know *what* they are; if we can assert their existence, we are ignorant as to their essence.

The name "agnosticism" was coined by Huxley about 1870 to distinguish this philosophical attitude from others, but the attitude had been professed before. It is, in fact, one of the issues of Kant's imposing theory of knowledge, and it had become, through the investigations of Sir W. Hamilton, Dean Mansel and Herbert Spencer, more sharply defined and more elaborately developed. Huxley, who was perhaps its most widely-known champion in the latter half of the 19th century, gave definiteness to its exposition by forcibly contrasting metaphysical and theological belief with scientific knowledge. We can now see that the controversial issue was confused, through failure at that time to realize that the word "knowledge" denotes not one sole psychological process and product, but several that are distinguishable; and also that what is called scientific knowledge is not quite so simple in its psychological structure, nor so logically "positive" in its nature, as the philosophically-inclined representatives of science in Huxley's day were wont to assume. The positivists who were led by the progress and prestige of physical science to regard science as constituted entirely by sense-data, linked together solely by relations such as could be read-off with the inevitableness and self-evidence of similarity, temporal sequence, etc., overlooked the fact, which had been clearly discerned by Hume, that we have no *logical* right to pass from our sporadic and evanescent sense-data, which yield evidence only as to here and now, to belief in a stable system of permanent things governed by law. The right is not a matter of logical necessitation but of psychological inevitableness; not of logical certification but of pragmatic verification; not of logical certainty but of personal certitude or sanguine confidence. Thus science is not knowledge, in the strict sense of reading-off, supplemented by logical inference. Such knowledge, and indeed the phenomenal objects about which it claims to know, are constituted such by suppositions that, in the first instance, are read *into* the data. Thus "knowing" means, in science of the actual, something different both from the immediate "acquaintance" of sense-perception and from the "truth" that is yielded by pure sciences, such as mathematics, whose "objects" are ideas—such as the line without breadth—and not actual things. This is also the doctrine of Kant. But Kant held that the reading-in that is involved in scientific knowledge is *a priori* necessary, so that such knowledge is knowledge in the strictest sense; whereas the reading-in that is involved in metaphysics and theology is but tentative and humanly expedient. This hard line between what Kant called understanding and reason—we might say between knowledge and mere belief—is now seen to be psychologically arbitrary, not so hard as he thought, and indeed to be drawn at the wrong place. Hence the rigid separation, once wont to be alleged between science and philosophy, and, on the strength of which, metaphysics and theology were disparaged, is no longer possible. The agnostic can no longer have that certainty as to the foundations of his science, in virtue of which he asserted nescience as to the non-phenomenal. The difference between the knowledge which he asserted and the knowledge which he disclaimed is one of degree of verifiability, not of kind or of intrinsic constitution.

But agnosticism, which issues out of Kant's phenomenalism, is imbued with consequences of what may be said to be another oversight of Kant, perhaps still more significant in import. Kant tried to work with the supposition that, though facts compel us to assert the existence of things *per se,* we can know no more about them. His doctrine implies that we can only know the phenomenal. This is the teaching that was developed by Hamilton into the dogmas that we can have no knowledge of the absolute or of ultimate reality, and no absolute or pure knowledge of anything: all knowledge is but relative. As to its Kantian foundation, it seems obvious that if we must posit things *per se,* in order to account for our sense-data being forthcoming, so must relations between things *per se* be posited to account for the stable connections between sense-data, which science elaborates into laws of nature. Indeed, unless we create most of our data out of nothing or out of our subjective states, etc., there must be structure and detail in the ontal corresponding to that which we observe in the phenomenal. Appearance cannot be appearance of nothing. Hence, instead of the Kantian formula, that we only know phenomena, it is more correct to say that we know the noumenal through the phenomenal. Thus there is not absolute nescience as to the noumenal, as agnosticism would assert. The most that can be urged is that we do not see the noumenal, so to say, through plate glass, but through the irremovable spectacles of the mind, which make a difference to the noumenal object or phenomenalize it. It is at this point that Hamilton's doctrine of the relativity of knowledge applies. He would regard phenomenal knowledge of the noumenal as not knowledge at all, because, in having it, we are not identical with the objects known nor become acquainted with them as they are in themselves. Our knowledge falls short of the ideal standard, in that it is impure—which is what he chiefly means by "relative." But it may be doubted whether knowledge suffers in value on that account. There is no reason to assume that, in imaging the real, the phenomenon veils it or caricatures and misrepresents it; it may reveal it, and reveal its significance just as effectually as would seeing face to face. What matters is that phenomenal knowledge should be *relevant* to reality, not that it should mirror its naked structure. An ordnance map serves all purposes of the tourist, though it may not mirror the coloured landscape or the geological formations of the district; it is relevant, if but appearance and not a copy. There is point-to-point correspondence between the lines and contours on the map and the streams, roads, gradients, etc., of the country which

it represents. Our phenomenal knowledge may bear—nay, must bear—much the same sort of relation as this to the realities which manifest themselves in and through the sensible and phenomenal. It enables us to "find our way about" our world, to be on terms of understanding with it and it may minister as much to spiritual wisdom as to practical prudence; for all that it is but phenomenal.

That "we see through a glass, darkly" may be our lot here: but it does not follow that we are wholly blind as to all that concerns our souls' health. Thus it would appear that agnosticism is superfluously modest. Its demurrer to the philosopher's claim that knowledge as to ultimate reality in general is inaccessible is not sustained.

If it would refuse the name of knowledge to such cognition it would seem to be cherishing a conception of knowledge to which no actually forthcoming "knowing" corresponds. For science itself, wont to be taken as the paradigm of knowledge, is at bottom interpretative, constructive, ejective and partly symbolical.

Its inductive method involves faith, for which there is reasonable, but not logical, justification And knowledge as to the objects with which metaphysics and theology are concerned, is but a further extension of the same method and the same sustaining faith as science uses, applied to such facts as evince meaning or purpose and value or significance, as well as to those which yield laws as to physical structure and connections.

BIBLIOGRAPHY.—J. Ward, *Naturalism and Agnosticism;* R. Flint, *Agnosticism* (1903). (F. R. T.)

**AGNUS DEI,** the figure of a lamb bearing a cross, symbolizing the Saviour as the "Lamb of God." The name is especially given in the Roman Church to waxen discs impressed with this figure and blessed by the pope. When first mentioned (*c.* 820) they were made of the remnants of the preceding year's paschal candle.

In modern times they are blessed on Easter Wednesday and distributed on the following Saturday, only in the first year of each pontificate and every seventh year after.

*Agnus Dei* is also the name for the invocation (based on John i, 29) *Agnus Dei, qui tollis peccata mundi, miserere nobis,* which appears to have been introduced into the Mass by Pope Sergius I (687–701).

It is there repeated thrice (the third time with *dona nobis pacem* for *miserere nobis*) between the Lord's Prayer and the communion: it is also appended to many of the litanies. The legality of its use in English, under certain conditions, in the Anglican communion service was upheld by the judgment in the Lincoln case (1890).

For the various ceremonies in the blessing of the *Agnus Dei, see* A. Vacant, *Dict. de Théologie* (cols. 605–613).

**AGOBARD** (*c.* 779–840), Carolingian prelate and reformer, became coadjutor to Leidrad, archbishop of Lyons, in 813, and on the death of the latter succeeded him in the see (816). Deposed in 835 by the council of Thionville, he made his peace with the emperor and was reinstated in 837. Agobard occupies an important place in the Carolingian renaissance. He wrote extensively not only theological works but also political pamphlets and dissertations directed against popular superstitions. He denounced the trial by ordeal of fire and water, the belief in witchcraft, and the ascription of tempests to magic, maintained the Carolingian opposition to image-worship, but carried his logic farther and opposed the adoration of the saints.

In his purely theological works Agobard was strictly orthodox, except that he denied the verbal inspiration of the Scriptures. Agobard was reverenced as a saint in Lyons, and although his canonization is disputed his life is given by the Bollandists, *Acta Sanctorum,* Jun. ii, 748.

BIBLIOGRAPHY.—Agobard's works were lost until 1605, when a manuscript was discovered in Lyons and published by Papirius Masson, again by Baluze in 1666. For later editions *see* Potthast, *Bibliotheca Historica Medii Aevi.* The life of Agobard in Ebert's *Geschichte der Litteratur des Mittelalters* (1880), is still one of the best to consult. For further indications *see* A. Molinier, *Sources de l'histoire de France.*

**AGONOTHETES,** in ancient Greece, the president or superintendent of the sacred games At first the person who instituted the games and defrayed the expenses was the Agonothetes. But in the public games, such as the Olympic and Pythian, these superintendents represented different States, or were chosen from the people in whose country the games were celebrated; thus at the Panathenaea at Athens ten *athlothetai* were elected for four years to superintend the various contests. They were variously called "regulators," "arbitrators," "judges of contests," "stewards of the games" (at Athens), "rod-bearers" (from the rod or sceptre emblematic of their authority), but their functions were generally the same.

**AGONY COLUMN,** a term often applied to the column in newspapers devoted to personal advertisements, such as announcements of losses or bequests. At as early a date as 1800 the "agony column" was a medium also for matrimonial advertisements It is sometimes known as the personal column

*See* Alice Clay, *The Agony Column of the "Times" 1800–1870* (1881).

**AGORA,** originally an assembly of the people of one of the Greek city States, called by the king or other authority to receive a decree or to discuss a policy. At an early period the word was used to describe the places where these meetings were held and in historic times any open space for general meetings, either official or commercial, was termed an agora. The agora of the historic Greek city was thus similar to the Roman forum or the mediaeval English market place. As the agora was the centre of the city life, it was surrounded by, or adjacent to the most important civic buildings, the prytaneum or official residence of the general, the basilica where the court sat, the *bouleuterion* or council hall, the thesaurus or treasury and the prison As the market place, it had ranges of sheds or colonnades for shops; frequently the colonnades were divided into parts, each named after the particular merchandise sold therein.

After the Persian wars the architectural treatment of the agora became much more monumental and lavish colonnades were frequently added to the older agorae, such as the Stoa of Attalus in the agora at Athens (between 159 and 138 B.C.). Of these later agorae many fine examples exist in various states of preservation. That at Ephesus was a square court over 500 ft. on the side, connected with additional courts containing a gorgeous nymphaeum and the lavish Roman library. At Priene the agora was traversed by streets but arranged so that through traffic was carried below on a detour. The substructures of the hillside agorae at Aegaea and Alinda still remain almost complete. In these cases the agora on a high terrace had large storage warehouses below. The great terrace wall at Alinda, with its striking rusticated masonry and large Roman arched openings, is especially impressive. Most important of all, however, is the agora at Assus, of which extensive remains still exist in a good state of preservation, with enough fragments to enable a complete and definitive restoration. This, like the two foregoing, is a hillside agora, supported on massive terrace walls. Its main architectural feature is the great two-storey portico.

The forum at Pompeii, in plan, dates probably from the time of the Greek colony. It therefore forms a connecting link between the Greek agora and the Roman forum. With its surrounding colonnade, its basilica, the city temple at one end and the civic offices at the other, it gives a perfect picture of what the typical Greek agora was like (For the agora at Athens *see* ATHENS.)

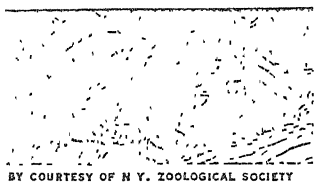
For a general discussion, *see* Cornish, *Dictionary of Greek and Roman Antiquities* (1898). The typical plan given is, however, absurd through its obvious misinterpretation of a passage in Pausanias in which he refers to colonnades separated by streets Pausanias plainly refers to streets traversing the agora and thus dividing the enclosing colonnade into separate sections *See* also S. H Bacon and Robert Koldewey, *Expedition of the Archaeological Institute of America* (investigations at Assus in 1881–83, 1902–21); Anderson and Spiers, *Architecture of Ancient Greece,* new ed. by W. B. Dinsmoor (1927).

**AGORACRITUS,** a Parian and Athenian sculptor of the age of Pheidias, and said to have been his favourite pupil. His most noted work was the statue at Rhamnus of Nemesis, by some

attributed to Pheidias himself. Of this statue part of the head is in the British Museum; some fragments of the reliefs which adorned the pedestal are in the museum at Athens.

**AGORANOMI.** Magistrates in Greece, whose duties were similar to those of the aediles of Rome. In Athens there were ten, five of whom took charge of the city and five of the Peiraeus. They maintained order in the markets, tested weights and measures, collected the harbour dues, and enforced the shipping regulations.

**AGORDAT,** a town of Eritrea, North-east Africa, on the route between Massawa and Kassala. It is connected by a railway, 194 miles long, with Massawa, via Asmara. At Agordat (Dec. 21, 1893) Italians under Colonel Arimondi defeated the followers of the khalifa. It was captured by British forces in March 1941.



**AGOSTINO** and **AGNOLO** (or ANGELO) **DA SIENA,** Italian architects and sculptors in the first half of the 14th century. Della Valle and other commentators deny that they were brothers They certainly studied together under Giovanni Pisano, and in 1317 were jointly appointed architects of their native town, for which they designed the Porta Romana, the church and convent of St. Francis, and other buildings. On the recommendation of Giotto (*q.v.*), they executed in 1330 the tomb of Bishop Guido Tarlati in the cathedral of Arezzo, which Giotto had designed. This monument was destroyed by the French under the duke of Anjou.

**AGOSTINO** or **AGOSTINI (AUGUSTINUS), PAOLO** (1593–1629), Italian musician, was born at Valerano, and studied under G. B. Nanini. He succeeded Ugolini as conductor of the pope's orchestra in St. Peter's. Among his compositions is an *Agnus Dei* for eight voices, once greatly admired.

**AGOULT, MARIE CATHERINE SOPHIE DE FLAVIGNY,** COMTESSE D' (1805–1876), French author, whose *nom de plume* was "Daniel Stern," was born at Frankfurt-on-Main on Dec. 31, 1805. Her father was a French officer who had served in the army of the emigrant princes, and her mother was the daughter of a Frankfurt banker. She was married in 1827 to the comte Charles d'Agoult. In Paris she gathered round her a brilliant society which included Alfred de Vigny, Sainte-Beuve, Ingres, Chopin, Meyerbeer, Heine and others. She was separated from her husband, and became the mistress of Franz Liszt. During her frequent travels in Switzerland, France and Italy she made the acquaintance of George Sand, and figures in the *Lettres d'un voyageur* as "Arabella." By Liszt she had three children—a son who died young; Blandine, who married Émile Ollivier; and Cosima, who married first Hans von Bülow and later Richard Wagner. The story of her breach with Liszt is told under a very slight disguise in her novel *Nélida* (1845). On her return to Paris in 1841 she began to write for the *Presse,* and later for the *Revue des deux Mondes* and the *Revue indépendante.* Mme. d'Agoult was an ardent apostle of the ideas of '48, and from this date her *salon,* which had been literary and artistic, took on a more political tone; revolutionists of various nationalities were welcomed by her, and she had an especial friendship and sympathy for Daniele Manin. In 1857 she produced a national drama, *Jeanne D'Arc,* which was translated into Italian and presented with success at Turin. The most important section of Daniel Stern's work is her political and historical essays. *Lettres républicaines* (1848), *Esquisses morales et politiques* (1849), *Histoire de la Révolution de 1848* (1850–1853), *Histoire des commencements de la République aux Pays-Bas* (1872). Mme. d'Agoult died in Paris March 5, 1876.

*See* Mme. d'Agoult, *Mes Souvenirs* (1806–33), 1877; J. Mazzini, *Lettres de Joseph Mazzini à Daniel Stern* (1872); A. Pommier, *Madame la comtesse d'Agoult* (Daniel Stern), 1876; A. Cuvillier Fleury, *Portraits révolutionnaires,* vol. i. (1889); A. Ungherini, "Daniel Stern" in the *Revista repubblicana* (1880, No. 9); S. Rocheblave, *Une Amitié romanesque, George Sand et Madame d'Agoult* (1895); R. Bory, *Une Retraite romantique en Suisse; Liszt et la comtesse d'Agoult* (1923), with an appendix containing letters; Daniel Oliver, *Mémoires de la comtesse d'Agoult: 1833–54* (1926).

**AGOUTI** or **AGUTI** (a-gōō-tĕ), rodent (*Dasyprocta aguti*), of the size of a rabbit, common to Trinidad and Guiana, and related to the guinea pigs. Agoutis are slender-limbed animals, with five front and three hind toes (the first front toe very minute), and short tails. The hair is coarse and rough; the colour being rufous brown. In habits agoutis are nocturnal, dwelling in forests, where they conceal themselves during the day in hollow tree-trunks, or in burrows among roots. They take readily to water and swim well. Their food comprises leaves, roots, nuts and other fruits. They do much harm to sugar-cane. (*See* RODENTIA.)

**AGRA,** the headquarters of a district, division and province of the same name in the United Provinces of Agra and Oudh (*q.v.*), was for long periods the capital city of India. Pop. (1941) 284,149. It stands on the Jumna which, though now at this point a mere trickle in the dry season, was formerly one of the chief arteries of commerce with the rest of India and at the same time a powerful frontier defence. Of the original Agra, which apparently lay on the left bank of the river, practically no traces remain. The present city on the right bank was the creation of the Mohammedan conquerors. The earlier dynasties fluctuated between Delhi and Agra as their centre of power; but it was at Agra that Sikander Lodi (A.D. 1500) set up his court, deeming it the strategic point for holding in check his turbulent vassals to the south. In 1526 the city was captured by Baber, the Koh-i-nor diamond being part of his booty. It was here that he decided to occupy India in permanence; here also that he died. It was his grandson Akbar who began to build the present fort (still by the people called Akbarabad), ruled India from within the walls, died in it, and was buried at Sikandra a few miles beyond the city gates. Agra fell from its pride of place when Aurangzeb moved to Delhi, and was never again the seat of monarchy. In the latter half of the 18th century, it was captured successively by the Jats, the Mahrattas, the Mohammedans and Scindhia; but it was finally taken by Lord Lake in 1803. After British rule was extended to upper India, it became the capital of the North-West provinces until at the close of the Mutiny the seat of that Government was transferred to Allahabad. The city is now a busy railway and commercial centre with cotton mills, gins and presses, flour mills and an important carpet industry.

There are two large colleges and several other educational institutions, including a medical school for men and women.

Although to travellers Agra is essentially the city of the Taj, it enshrines several other magnificent specimens of Mogul architecture, each perfect of its kind. The fort, with its lofty walls of red sandstone 1½m. in circumference, contains at least two such gems. Separated from each other by the main block of the buildings of the imperial court, stand on the north the Pearl Mosque, built by Shah Jahan, and on the south the Jahangiri Mahal or palace built by Akbar; the former unequalled for the beauty and purity of its proportions, material and constructive design in simple white marble; the latter a perfect adaptation of stately solidity and commanding symmetry of the Hindu style. If we leave the fort and cross the river, we find another gem of its kind in the tomb of Itmad-ud-Daulah, father of Jahangir's empress. Its architecture is transitional between the virile conceptions of Akbar and the poetic richness of Shah Jahan; elegant, elaborate and scholarly, it was the first triumph of marble inlaid work in direct imitation of Persian pottery decoration. Five miles from Agra is Sikandra, where Akbar was buried, though his remains were desecrated and scattered by Jat freebooters in later years. His tomb is a noble building in a noble setting, and the marble sarcophagus on its roof is strikingly impressive in its simple dignity. Far exceeding all the others in glory is the Taj, the most beautiful mausoleum in the world. It was built by Shah Jahan for his empress, who died in A.D. 1631; and from one of her titles, Taj Mahal or Crown of the Palace, it takes the name by which it is most generally known outside India. Built of pure white marble, it stands on a vast marble terrace, crowned by a great dome in the centre and smaller domes at each of its corners. From the angles of the terrace rise

four slender minarets. Subservient and supplementary to the glory of the outline is the beauty of the ornamentation. "All the spandrils of the Taj," writes Fergusson, "all the angles and more important architectural details are heightened by being inlaid with precious stones such as agates, bloodstones, jaspers and the like. These are combined in wreaths, scrolls and frets as exquisite in design as they are beautiful in colour, and relieved by the pure white marble in which they are inlaid, they form the most beautiful and precious style of ornament ever adopted in architecture."

The architect of the Taj was Ustad Isa, variously described as a Byzantine Turk, and as a Persian from Shiraz. The artificers engaged during the 17 years of its construction came from all

THE TAJ MAHAL AT AGRA, ERECTED BY THE EMPEROR SHAH JAHAN AS A MAUSOLEUM FOR HIS EMPRESS WHO DIED IN A.D. 1631. THE ARCHITECT WAS USTAD ISA

parts of Asia and probably included a French goldsmith, Austin de Bordeaux.

The district of Agra has an area of 1,861 sq.mi. Its general appearance is that common to the Doab, a level plain intersected by watercourses with fringes of ravines. Its general elevation is estimated at from 650 to 700 ft above the level of the sea. The district is intersected by the Jumna, and is also watered by the Agra canal. The principal crops are millets, pulses, barley, wheat, cotton and a little indigo. The population in 1941 was 1,289,774

The division of Agra has an area of 8,646 sq mi. In 1941 the population was 5,326,768. It comprises the five districts of Aligarh, Muttra, Agra, Mainpuri and Etah

**AGRA CANAL,** primarily an irrigation project opened in 1874, but widely used for navigation It is supplied with water from the Jumna river and beginning at Okla, 10 m. below Delhi it passes through the districts of Delhi, Gurgaon, Muttra and Agra as well as the Bharatpur state. It finally joins the Banganga river about 20 m. below Agra.

**AGRAM:** *see* ZAGREB

**AGRAPHA,** the name given to certain utterances ascribed, with some degree of certainty, to Jesus, which have been preserved in documents other than the Gospels, *e.g.*, Acts xx. 35; 1 Tim. v. 18; 1 Cor. vii. 10–12, and the Logia (*q.v.*) discovered in 1897 and 1903 at Oxyrhynchus.

BIBLIOGRAPHY.—*See* A. Resch, *Agrapha* (Leipzig, 1889); J. H. Ropes, *Die Spruche Jesu* (Leipzig, 1896); and the article "Sayings" in J. Hastings's *Dictionary of Christ and the Gospels.*

**AGRARIAN LAWS,** law dealing with the disposal of the public land (*ager publicus*) of ancient Rome No gratuitous disposition of state property could be made without the consent of the people. Hence many of the ordinances affecting the public land were laws (*leges*) in the strictest sense of that word. It is, however, convenient to consider in this article all the regulations that were made for the administration of the public land by the executive authorities, as well as by the people during the republic, and by the commands of the emperor. These had the force of law during the principate

Public land was the prize of conquest and was one of the means of defraying the expenses of state administration. For this purpose land was often leased on the condition of the payment of dues. But it was made to fulfil another purpose, the satisfaction of the individual needs of poorer citizens. To this end land was assigned, and on assignment ceased to be the property of the state. But it often happened that the state was not disinterested in such acts of assignment It gained security and territorial control by planting garrisons in conquered country, and it relieved itself of the necessity of providing for its poorer classes by state-aid. The connection between agrarian legislation and colonization can be seen at once, and also the two aspects of colonization—the military and the social. These two objects were connected throughout the whole of the earlier period of Roman agrarian assignation. After the time of the Gracchi social motives continued to be operative when military precautions had ceased to be necessary One of the motives which prompted infant Rome to war with her neighbours was the land-hunger of her citizens. This hunger she satisfied after conquest by annexing a portion of the enemy's territory. The amount thus confiscated varied. It was usually a third, but sometimes a half or even two-thirds, and after the fall of Capua in the Second Punic War the whole territory of the state was annexed. By the close of the 2nd century B.C. one-half of the land of Italy belonged to Rome whether in private ownership or as the property of the state. Annexation was carried on in the provinces on a smaller scale; but Rome retained as domain-land much of the territory of communities which had been destroyed (*e.g.*, Carthage and Corinth), and the estates of former kings. This peculiar property of the Roman state in the provinces must be carefully distinguished from the general overlordship which Rome was supposed to hold over all provincial soil, expressed in the statement that provincials had only possession or usufruct of land.

**Methods of Handling Public Land.**—Such portions of the territories of conquered cities as were not claimed by Rome were left in the possession of these cities. If the city was a federate state (*civitas foederata*) this possession was guaranteed by a treaty; if it was a free city, the guarantee was made by charter; where Rome had marked out territory for assignment to her own citizens, but where, in or near the limits of the assignment, some of the land had been left in the hands of its former proprietors, such land was noted in the state registers as *redditus veteri possessori.*

The State dealt in two ways with such land as it retained. It alienated it, in exchange for a price or gratuitously; or it kept it as a source of revenue, whether on lease or on some system of remunerative occupation. The land might be sold for the benefit of the treasury. Typical instances of this treatment are furnished by the sale of some Campanian land during the Second Punic War. The censors may have directed the sale, but it was executed by the quaestors as the regular officials of the treasury. Hence such land was described as *ager quaestorius.* The land was sold in definitely marked out plots, and when this sale had been effected the lots fell under the absolute ownership of their purchasers.

The second mode of alienation was that by assignation. Lands thus assigned were known as *agri dati adsignati.* The gift on the part of the State was gratuitous, and ownership passed wholly to the assignee. The land so given was definitely surveyed, marked out, and registered. Such an assignment might take one of two possible forms. It might be the means of establishing a new "plantation" (*colonia*), with some independent organization of its own, or it might be the means of providing allotments for individuals who remained domiciled at Rome or in some already existing municipality. The amount granted to individuals in assignments of both types varied from time to time It was reckoned in terms of the *iugerum,* which was approximately five-eighths of an English acre. The earliest and smallest assignment was two *iugera:*

14 *iugera* was the maximum amount granted before the time of Ti. Gracchus (133 B.C.), and it was held by representatives of the old school that seven *iugera* were as much as any frugal Roman should want. The division was carried out by commissions appointed by the people. The land which the State retained as *ager publicus* was always placed in the hands of individuals, who occupied it in some manner remunerative to the State These individuals (*possessores*) were never regarded as owners of the land thus occupied. It remained the property of the State, was held without a contract (*precario*), and could be resumed by the State at will. But though the tenants had no claim against the State, their ownership could be defended against all other claimants; from an early date the praetor's possessory interdict was used to protect all occupiers, provided their tenure had not been acquired by force (*vi*), by seizure of land in its occupiers' absence (*clam*), or by mere permission of the previous holder to occupy (*precario alter ab altero*). Tenants of this type could transfer their land by inheritance, and the land was accepted as security by creditors. This kind of occupation, therefore, though clearly distinguished from ownership (*dominium*), was yet regarded as a perfectly secure form of tenure. All occupiers of public land paid dues to the State through a state contractor (*publicanus*). These dues varied in amount and in the method of their collection. We learn from Appian that the ordinary dues paid by occupiers of arable land in Italy were one-tenth of seed crops and one-fifth of plant produce. Owners who turned cattle or sheep on pasture land belonging to the state also paid fixed dues to the treasury. The occupiers of the Roman public land in Campania paid a large rent. The conditions of the tenure of the Roman public land in Africa are known to us from the *Lex Agraria* of 111 B.C. The *publicanus* is the middleman between the State and the *possessor* and purchases from the censor the right of collecting dues. The law places no restriction on bargaining between the censor and the *publicanus,* but enacts that no *possessor* or *pastor* shall ever be required by the *publicanus* to pay more than the amount prescribed by the censors of 115 B.C. These conditions may be regarded as typical for the occupation of public lands. When Cicero speaks of public land as let on lease (*locatus*) by the censor, he refers to the leasing of the taxes to a *publicanus* for a fixed period, and not to the letting of the land. This seems clear from a passage (*In Verr.* iii. 6. 12) where he speaks of land in Sicily which had been restored by Rome to former owners as being leased. The land itself could not be leased by Rome if it belonged not to Rome but to the Sicilian inhabitants; but the collection of the revenues due to Rome could be so leased to *publicani* (*q.v.*). The same explanation would apply to Cicero's statements that the Campanian land was let on lease by the censors. Cicero's repeated statement that the Campanian land was expressly exempted from the legislation of the Gracchi shows that there was not sufficient distinction between the Campanian tenure and that of other public land in Italy to make this definite exception by name superfluous. The Sempronian law could obviously not touch land which the State had leased to occupiers on the basis of a definite contract. It seems certain that in every case the *possessor* occupied *precario,* and that only in the bargain between the censor and the middleman was there room for contract. Thus the State was justified in the claim to resume public land which it made in many of the agrarian laws.

**Survey of Agrarian Legislation.**—The earliest agrarian measures of which we have any record are the distributions to poor citizens of land conquered in war, which later authorities attribute to Numa and Servius Tullius. Such assignments were a voluntary surrender on the king's part of his own portion of the spoils. The agrarian law of Spurius Cassius (486 B.C.) distributed *ager publicus* among the plebeians. Another agrarian law proposed by the tribune Lucius Icilius in 456 B.C. regulated the tenure of public land on the Aventine. In 376 B.C. the tribunes Licinius and Sextius introduced into their laws, for the promotion of the privileges of the *plebs,* a clause enacting that no more than 500 *iugera* of land should be occupied by a single cultivator; the law also enacted that only 100 cattle and 500 sheep might be turned by one owner on the public pastures. But it failed of its object because it did not provide any adequate machinery for the resumption by the state of land held in excess of the prescribed amou therefore easily evaded. The next agrarian law wa dealing with lands conquered from the Senones (*q v.* tines. In 232 B C C. Flaminius, tribune of the *plebs,* pro resume these lands for the state, although they were already occupied by large landholders, and to distribute them in allotments to poor citizens. The measure met with much opposition from the richer classes, and did not gain the sanction of the senate; but C. Flaminius ignored constitutional usage and brought it direct before the council of the *plebs,* by which it was made law. In 133 B C. the tribune Tiberius Gracchus (*q v.*) re-enacted the earlier measure of Licinius and Sextius, with the additional provisions that each owner might occupy 250 *iugera* for each son, in addition to the original 500, and that a commission of three (*III. viri agris dandis adsignandis*) should be appointed to carry out the terms of the law He also enacted that the land occupied in excess of the prescribed amount, and on that account resumed for the State by the land commission, should be distributed in inalienable lots to poor citizens. Subsequent modifications of those provisions which dealt with the powers of the land commission led to a re-enactment of the whole by G. Gracchus (*q v.*), the brother of Tiberius, tribune in 123 B C But within 15 years from the tribunate of G. Gracchus the whole of his law had been rendered null by three further enactments. The first of these permitted the sale of land allotted under the law, which thus tended to return into the hands of its former occupiers as private property, which the State had no longer any right to resume. The second abolished the commission appointed to carry out the terms of the law, thus putting a stop to further resumption and distribution, and also transformed existing occupiers into owners of the land they occupied, paying only a small due to the treasury. The third abolished the payment. That law belonged to the year 111 B.C.

From that time forward a change came over land legislation. The ordinary public land in Italy, in the hands of occupiers, which had given rise to all the agrarian legislation between 376 and 111 B.C. had practically ceased to exist. The Campanian land still remained, but the same reasons which led to [illegible] from the Gracchan legislation seem to have continued to protect its holders until 63 B.C In the meantime several agrarian laws were passed which provided for the distribution of land placed in some other way at the disposal of the State. In 100 B.C. Appuleius Saturninus (*q.v.*) tribune, proposed the allotment of lands recently taken from the Cimbri in Gaul. This law was passed but eventually declared null by the senate, with the rest of Saturninus's laws. A more dangerous precedent was set by Sulla in his dictatorship (82–81 B.C.). He was the first to confiscate the lands of his political opponents and of communities which had resisted him and, treating them as *ager publicus,* assign them to his veterans as a prize. This example was followed by Octavian (Augustus) and Antony (M. Antonius) after their proscriptions in 43 B.C. A third method of providing land for distribution was that adopted by Servilius Rullus (*q.v.*) in 63 B.C. His bill enacted that land should be purchased in Italy with money gained by the sale of Roman territories abroad, and allotted to citizens. A commission of ten (*X. viri agris dandis adsignandis*), annually elected by nine out of the 35 tribes, was to carry out the terms of the law. Rullus also ventured to propose the distribution of the Campanian land which had hitherto been respected by all agrarian reformers. It was chiefly on this ground that Cicero in his three speeches on the Agrarian law succeeded in exciting such a general feeling against it that it was eventually withdrawn. In 60 B.C. the tribune L. Flavius brought forward a bill for the distribution of lands to Pompey's veterans. The Campanian land was certainly to be included in the distribution, and it is clear from Cicero that the bill in some way dealt violently with the rights of private owners. It also, however, enacted that land should be purchased by the State with the wealth which Pompey's conquests had brought into the treasury. The last proposal was supported by Cicero, but the bill seems to have been dropped, only to reappear in more moderate form in the following year. A consular bill, the *lex Iulia Campana,* was passed by Julius Caesar in 59 B.C., which provided for the settlement of Pompey's veterans on the Campanian land, and other lands pur-

based by the state from private owners in Italy with the full consent of the latter. In its original form, the bill omitted all reference to the Campanian land, which seems to have been included by Caesar in the distribution only when the continued and unreasoning opposition of the senate had goaded him to extreme measures. A commission of twenty was to be appointed to carry out the law, from which Caesar himself was expressly excluded. This measure finally settled the question of the Campanian land, which now passed out of the category of *ager publicus*. The last agrarian law of the republic was that passed in 44 B.C. on the proposal of the consul M. Antonius. We have no detailed account of the measure, but it seems to have provided grants of land for veterans, and was to be administered by seven commissioners. The law was afterwards cancelled by decree of the senate.

**AGRARIAN MOVEMENT:** *see* LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS.

**AGREDA, MARIA FERNANDEZ CORONEL,** ABBESS OF, known in religion as Sor (Sister) Maria de Jesus (1602–1665), was born at Agreda, on the borders of Navarre and Aragon, on April 2, 1602. All her family were powerfully influenced by the ecstatic piety of Spain in that age. From childhood she experienced ecstasies and visions. When she was fifteen the whole family entered religion. Maria, her mother and sister established a Franciscan nunnery in the family house at Agreda, which, when Maria's reputation had extended, was replaced by the existing building. She began it with one hundred reals (one pound sterling) lent her by a devotee, and it was completed in fourteen years by voluntary gifts. Much against her own wish, we are told, she was appointed abbess at the age of 25. Though the rule required the abbess to be changed every three years, Maria remained the effective ruler of Agreda till her death. In the earlier part of her life, while the Franciscan, Francisco Andres de la Torre, was her confessor, she wrote an *Introduction to the History of the Most Blessed Virgin.* It was destroyed by the direction of another confessor. Later on, under the guidance of her Franciscan confessor, Andres de Fuen Mayor, she wrote *The Mystic City of God.* It is an extraordinary book, full of apocryphal history, visions, and scholasticism. In 1642 she sent to Philip IV. an account of a vision of a council of the infernal powers for the destruction of Catholicism and Spain. The king visited her when on his way to Aragon to suppress the rebellion of Catalonia. A long correspondence, which lasted till her death on March 29, 1665, was begun. The king folded a sheet of paper down the middle and wrote on the one side of the division. The answers were to be written on the other and the sheet returned. How far Maria was only the mouthpiece of the Franciscans must of course be a matter of doubt. Her correspondence was apparently suspended whenever her confessor was absent. The letters are in excellent Spanish, are curious reading, and are invaluable as illustrations for the second part of the reign of Philip IV.

The correspondence of Sor Maria with the king has been published in full by Don F. Siluela, *Cartas de la Venerable Madre Sor Maria de Agreda y del Señor Rey Don Filipe IV.* (1885). *The Mystic City of God* continued to be much in favour with supporters of the dogma of the Immaculate Conception. It appeared in Madrid in 1668, with a biographical introduction by Samaniego, has been often reprinted, and was translated into French and Italian. It was for a time reserved by the Index, both Spanish and Papal, but was taken off by the influence of the Franciscans and of Spain, the chief supporters of the Immaculate Conception. An account of Maria de Agreda will be found in the *Tracts* of Michael Geddes (1706), vol. iii., written by a competent critic and Anglican divine of the 18th century who detested "enthusiasm."

**AGRÉMENTS** (Ital. *abbellimenti;* Ger. *Manieren;* Eng. *ornaments*), in music, are supplementary notes, or embellishments, introduced for the purpose of enriching, elaborating or otherwise altering the effect of the phrase or melody to which they are applied. As employed in connection with the older types of music, alike vocal and instrumental, they assumed a large variety of forms (acciaccatura, appoggiatura, arpeggio, mordent, shake, turn, and so on) which in course of time became definitely standardized and so formed an essential part of the music, although nominally left to the discretion of the performer and indicated, if at all, only by conventional signs.

**AGRIANES,** a warlike tribe anciently inhabiting Upper Macedonia, and part of what is now south-western Bulgaria. They provided some of the most active and dangerous of the troops of Alexander's army, distinguishing themselves at the Granicus, Issus and on the banks of the Jhelum.

**AGRICOLA, GEORGIUS** (GEORGE BAUER) (1494–1555), German scholar and man of science, known as "the father of mineralogy," was born at Glauchau in Saxony on March 24, 1494 After studying philology at the universities of Leipzig, Bologna and Padua, he earned a degree in medicine at the University of Ferrara. From 1527 to 1533 he was city physician in the flourishing mining town of Joachimsthal in Bohemia and from 1534 to the end of his life [illegible] in Chemnitz. He adopted the Latinized form of his name and wrote in Latin. Although he made contributions to medicine, mathematics, theology and history, his most important writings were on mineralogy and mining. Living in what was then the greatest mining region in Europe, and in close touch with all phases of the industry, his intimate and practical knowledge enabled him to become the first writer on these subjects to rely on direct observation rather than on speculation. He exerted a direct influence on his contemporaries and successors and through them on the development of geological science. Best known of his six books on geological subjects is *De re metallica,* published posthumously in 1556. It deals chiefly with the arts of mining and smelting and contains many informative and attractive woodcuts.

In his *De natura fossilium* (1546), translated into German by Ernst Lehmann (Freiberg, 1809–10), and considered the first mineralogy textbook, he presented a new classification of minerals based on their physical properties, and described many new minerals, chiefly metallic ores, their occurrence and mutual relationships. His first mineralogical work, *Bermannus, sive de re metallica dialogus* (1530), a treatise on the Erzgebirge mining district, was translated into English by Herbert Hoover and his wife. In *De ortu et causis subterraneorum* (1546) he recognized clastic rocks and mineral-bearing solutions. His other geological works are *De natura eorum quae effluent ex terra* (1546) and *De veteribus et novis metallis* (1546). He died Nov. 21, 1556.

**AGRICOLA, GNAEUS IULIUS** (A.D. 37–93), Roman general, father-in-law of the historian Tacitus, was born on June 13, A.D. 37 (according to others, 39) at Forum Iulii (Fréjus) in Gallia Narbonensis. His grandfathers were of equestrian rank; his father became a senator, but was put to death by Caligula. Agricola was brought up by his mother at Massilia. He entered the army and served (59) under Suetonius Paulinus in Britain. In 61 he returned to Rome, where he married Domitia Decidiana, a Roman lady of distinction. In 63 he was quaestor in Asia, in 65 tribune, in 68 praetor, and when Vespasian was proclaimed emperor, he immediately declared himself his supporter. In 70 he was appointed to the command of the 20th Legion in Britain, then stationed at Deva (Chester). On his return to Rome, at the end of three years, he was made censor, raised to the rank of patrician, and appointed governor of Aquitania (74–78). Appointed *consul suffectus* in the following year, he was admitted into the college of pontiffs and made governor of Britain. In the same year he betrothed his daughter to Tacitus.

Agricola spent at least seven years in Britain. After conquering the Ordovices in North Wales and the island of Mona (Anglesey), during the next two years he advanced to the Taüs (Tay; others read Tanaus, perhaps the north Tyne), and in his fourth campaign fortified the country between Clota and Bodotria (the firths of Clyde and Forth) as a protection against the attacks of the Caledonians. Having explored the coasts of Fife and Forfar, he gained a decisive victory over the Caledonians under Galgacus at the

Graupian hill. (*See* BRITAIN: *Roman*) Between campaigns he busied himself in helping forward the Romanization of his province. But his successes had aroused the suspicion of Domitian. He was recalled to Rome, where he lived in retirement, refusing the proconsulship of Asia. He died in 93, poisoned, it was rumoured, by the emperor's orders.

Mommsen, *Provinces of the Roman Empire*, tr. by W. P Dickson, vol. 1, pp. 183–184, 194 (1887); C. [illegible] *Historical Works of Tacitus*, tr. by A. Murray (1932).

**AGRICOLA, JOHANNES** (originally Schneider, then Schnitter) (1494–1566), German Protestant reformer, was born April 20, 1494, at Eisleben, whence he is sometimes called *Magister Islebius*. He studied at Wittenberg, where he met Luther. In 1519 he accompanied Luther to the great assembly of German divines at Leipzig, and acted as recording secretary. He taught and preached the Lutheran doctrine in Frankfurt, Eisleben and Wittenberg, but in 1536 an old controversy broke out more violently than ever. Agricola was the pioneer of the Antinomian heresy, which maintained that while the unregenerate were still under the Mosaic law, Christians were entirely free from it, being under the gospel alone. During the bitter controversy with Luther that followed, Agricola in 1540 left Wittenberg secretly for Berlin, where he addressed a letter to the elector of Saxony, which was generally interpreted as a recantation of his views. Luther, however, was not satisfied, and Agricola remained at Berlin, where Joachim II of Brandenburg appointed him court preacher and general superintendent. With Julius von Pflug and Michael Helding, he prepared the Augsburg Interim of 1548. He endeavoured in vain to appease the Adiaphoristic controversy (*see* ADIAPHORISTS). He died during an epidemic of plague on Sept. 22, 1566.

**AGRICOLA, RODOLPHUS** (properly ROELOF HUYSMANN) (1443–1485), Dutch scholar, was born at Baflo near Groningen, Aug. 23, 1443. He was educated at Louvain, Paris, and at Ferrara, where he attended the lectures of the celebrated Theodorus Gaza (1400–78) on the Greek language. In 1482, on the invitation of Johann von Dalberg, bishop of Worms (1445–1503), he accepted a professorship at Heidelberg, and for three years delivered lectures there and at Worms on the literature of Greece and Rome. By his personal influence more than by his writings he did much for the renaissance of learning in Germany; and Erasmus and other critics of the generation immediately succeeding his are full of his praises. He died at Heidelberg on Oct. 28, 1485. His principal work is *De inventione dialectica, libri iii*, in which he attacks the scholastic philosophy of the day. His collected works were edited by Alard (Cologne, 1539).

**AGRICULTURAL ARTICLES.** Agriculture is treated in these pages under various headings, an enumeration of which will help the reader to consult any part of the subject.

For a general account of agriculture, reference should be made in the first place to the articles AGRICULTURE: A GENERAL SURVEY; AGRICULTURE, PRIMITIVE; FARM; GARDEN; HORTICULTURE; and to the sections on agriculture appended to the articles on the different countries.

As to the operations on agriculture, *see* the articles AGRICULTURAL ENGINEERING; AGRICULTURAL POWER AND MACHINERY; ARABLE; BAULK OR BALK; CROP-DRYING; CULTIVATION; ELECTRICAL POWER IN AGRICULTURE; FALLOW; FARM BUILDINGS; FERTILIZERS; FLAIL; FORK; GUANO; HARVEST; HARVESTING MACHINERY; LAND RECLAMATION; LIMING; LOAM; OPEN-FIELD SYSTEM; PLANT BREEDING; PLANTING MACHINERY; PROCESSING MACHINERY; REAPING; ROTATION OF CROPS; SOIL; SOWING; SPRAYING AND DUSTING MACHINERY; THRASHING OR THRESHING; TILLAGE; TILLAGE MACHINERY; TRACTORS.

The business and organization of agriculture will be found treated under AGRICULTURAL CO-OPERATION; AGRICULTURAL CREDIT; AGRICULTURAL ECONOMICS; AGRICULTURAL EDUCATION; AGRICULTURAL INSURANCE; AGRICULTURAL ORGANIZATION; AGRICULTURAL RESEARCH; FARM MANAGEMENT (including farm organization and equipment); and FARM VALUATIONS.

LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS is treated under that heading, and there are articles on ALLOTMENTS; FARM RENTS; and SMALL HOLDINGS. The various institutions connected with agriculture are treated under the headings AGRICULTURAL SOCIETIES AND SHOWS; AGRICULTURE, CHAMBERS OF; AMERICAN FARM BUREAU FEDERATION; FARM COLONY; FARMERS' CLUBS, FARMERS' ORGANIZATIONS, FARMERS' UNION; GRANGE, THE; INTERNATIONAL CONFERENCE OF AGRICULTURAL ECONOMISTS; and INTERNATIONAL INSTITUTE OF AGRICULTURE. For a discussion of farm relief legislation after 1928 in the United States *see* FEDERAL FARM BOARD. For statistics *see* AGRICULTURAL PRICES; AGRICULTURAL STATISTICS: and AGRICULTURE, CENSUS OF.

As to agricultural employment, the articles AGRICULTURAL GANGS; AGRICULTURAL LABOURER; and AGRICULTURAL WAGES should be consulted. Coming to agricultural production, in addition to general articles entitled AGRONOMY; ARVICULTURE; CEREALS; COTTON AND THE COTTON INDUSTRY; CROPS; GRAIN PRODUCTION AND TRADE; SUGAR; and WHEAT, there is an article on GRASS AND GRASSLAND which includes the discussion of hay crops and pastures.

As to animals, articles may be consulted on ANIMAL BREEDING; BRANDING; BREEDS AND BREEDING; CATTLE; HORSE; MERINO; OX; PIG; SHEEP; and STOCKYARDS.

There are articles on ENSILAGE; FEEDING STUFFS AND LIVESTOCK FEEDING; and FORAGE. Articles will be found on ARBOR DAY; ARBORICULTURE; BEE; COPPICE OR COPSE; CREAMERIES; DAIRY FARMING; EGG, ESPALIER; FORESTS AND FORESTRY; FRUIT FARMING; HONEY; POULTRY AND POULTRY FARMING; TOBACCO; TREE; and TURKEY.

There is a special article on TROPICAL AGRICULTURE.

**AGRICULTURAL CO-OPERATION.** The development of agricultural co-operation has taken widely different courses in various countries according to their specific needs. The main difference to be observed is between countries which are primarily producers of agricultural commodities for export, and those which produce mainly for home consumption. In the former, the co-operative movement has chiefly concentrated upon the organization of marketing; in the latter—apart from the development of rural credit and insurance—mainly upon the purchase of farm requisites, or the formation of co-operative dairy, bacon or other producing societies. Although this broad distinction holds good, it is nevertheless true that practically all types of co-operation are to be found to a greater or lesser extent in the principal agricultural countries.

**Co-operation in Great Britain.**—Agricultural co-operation in Great Britain may be said to have begun with isolated experiments during the 19th century, but very little resulted from these early attempts. The Agricultural Organization society in 1901 was the centre of the movement from its formation until it was wound up in 1924. During this period a great many societies were established.

The period following the war of 1914–18 brought forth a considerable intensification of the efforts to promote co-operation amongst British farmers, and the Agricultural Organization Society was assisted by grants from the state. A number of new societies were formed between 1918 and 1924. Unfortunately these efforts met with only limited success, and the creation of new societies was largely offset by a considerable number of failures. This was due to several factors—to the rapid fall in agricultural prices which took place after the spring of 1920, to the fact that a large number of the new societies were small and financially weak and were therefore unable to secure competent management, to the failure of many societies to adopt certain principles in co-operation which in other countries had proved to be essential, and

to the lack of interest shown by farmers themselves

Among agricultural co-operative societies in Great Britain the most successful have been the relatively large-scale societies concerned with the supply of farm requisites, a few dairy societies, and a certain number of others engaged in the sale of eggs, wool, fruit and vegetables, etc. Mention should be made of the formation of the Agricultural Wholesale Society in 1918, which was an attempt to provide a central wholesale organization from which the local requisite societies could obtain their supplies; its relation to the latter was similar to that between the co-operative wholesale societies and the retail consumers' co-operative societies. Such central wholesale societies had for some years been an integral part of the agricultural co-operative organization in several European countries.

**Co-operation in Europe.**—In western Europe, where the majority of countries were importers of food or were approximately self-supporting, the growth of co-operation was mainly in the direction of developing rural credit societies (*see* AGRICULTURAL CREDIT) or of societies for the purchase of agricultural requisites, though often combining these functions with that of the sale of produce. But even here, Denmark, conducting a considerable export trade, developed its marketing organizations on co-operative lines in addition to its highly organized system of supply societies; indeed it has been the model upon which many of the marketing organizations in the newer countries have been based. Leadership in agricultural co-operation has belonged to Germany and Denmark.

A general characteristic of the European co-operative movement is that both in its origin and subsequent development there has been a certain idealism which has given it a special vitality Thus, in Denmark, the movement was associated with a moral educational revival accompanied with the development of the people's high schools; in Belgium the co-operative organization had a basis of religious and social culture; in Germany the birth of the co-operative credit movement was largely a question of the social regeneration of the rural population. In most of these cases it started with the clubbing together of a small number of villagers to carry out a common object, whether it was the purchase or sale of produce, or the provision of credit. But, although built up upon this small foundation, the movement gradually assumed a different character through the consolidation of the small units into large federated organizations, the gradual centralization of control, and the development of many of the features of big-scale enterprise. Indeed, federation describes in a word the modern development of the co-operative movement in most agricultural countries.

The main divisions of the co-operative movement in Europe have been supply, production, marketing, credit and insurance. Other minor, but important, branches are the co-operative use of farm machinery, cattle breeding, the supply of electric light and power, the manufacture of potato meal and potato alcohol, forestry and fishing.

**Supply Societies.**—These have aimed at purchasing agricultural requisites in bulk at wholesale prices and delivering them to members at cost. They have been widely developed upon "Rochdale" principles, the goods being delivered to members at certain fixed prices and the profits of the societies being distributed amongst its members as a "dividend" in proportion to the gross amount of their purchases This principle applies in many European countries, though an exception is to be found in France, where the profits of the "syndicats" go to the formation of a reserve fund which belongs to the members equally, irrespective of the amount of their purchases. The tendency in the development of these societies is to federate the local distributive societies to central wholesale societies on the general plan of the British distributive movement.

In Germany, the pioneer society in the movement towards wholesale federation was the Haas Society at Insterburg, founded in 1871. This example was subsequently followed by the rest of Germany, membership of the provincial wholesales being usually confined to the local distributive societies. The first permanently successful federation amongst consumers' stores in Denmark started in 1884 with the formation of the Co-operative Wholesale Society of Denmark amongst the societies on Zealand (Själland), for the supply of farm requisites as well as ordinary household requisites. Four years later a similar wholesale society was started in the Jutland Peninsula, and in 1896 these two were amalgamated into one organization—the Co-operative Wholesale Society of Denmark. Since then it has made remarkable growth.

In Switzerland similar progress has been made. The Verband-Ost-Schweizerischer - landwirtschaftlicher - Genossenschaften was formed as a central society. The business was divided into two departments—the agricultural, dealing with seeds, manures, cattle food, etc., and the store department, dealing with household requisites The organization also undertook the sale of members' produce, though its supply side remains its more important function. In France, the local, and more particularly the communal, "syndicats agricoles," united in departmental unions, and these unions formed the starting point of larger organizations—the "unions regionales."

**Production Societies.**—Probably the most successful branch of productive co-operation is to be found in the dairy societies existing in large numbers in all countries in which agricultural co-operation is firmly established. Leadership belonged to Germany and Denmark. Switzerland, France, Holland, Belgium and some of the countries of south-eastern Europe have also made considerable progress. Ireland, too, was one of the most successful countries in developing co-operative creameries. (*See* CREAMERIES.)

Mention should be made of the bacon factories and egg and poultry societies, the former of which have been brought to a high degree of efficiency in Denmark. These are factories requiring a considerable amount of capital and provided with subsidiary plants for the disposal of by-products. They are usually financed by loans jointly and severally guaranteed by the members, and receive the pigs from members under contracts binding them to supply their whole output for a period of years. The individual bacon factories are federated in the National Federation of Danish Co-operative Bacon Factories, with head offices in Copenhagen. One of the most remarkable achievements of this co-operative organization is the improvement of breed which it has enabled producers to bring about. A close study of the requirements of the British market (the principal export market) combined with scientific pig [illegible] under the supervision of the Government and the National Federation of Co-operative Bacon Factories, has led during the last 40 years to an improvement in quality, without parallel in other countries.

**Marketing.**—To Denmark also belongs the credit of beginning co-operative marketing. The tendency was to establish strong central selling or export agencies of which local productive societies were members. The need for co-operation among the local co-operative societies gave the impulse towards the centralization of marketing, and the formation of provincial and ultimately national associations, but many difficulties were experienced before the structural development of the marketing organizations was complete. The turning point was reached when the principle of binding contracts for the supply of produce was adopted. Under this system the members of a local co-operative marketing association undertook to supply the whole of their produce to their society for a term of years. The term ranged from one to as many as 20 years. On this firm foundation it has been found possible to build up the modern organization which markets the greater part of Danish agricultural produce. The local units, having a democratic membership control, are usually federated to the central society on "commodity" lines, that is to say, the federation of local societies is usually concerned with one agricultural commodity or commodities of closely allied character. Members are paid for produce by an advance at the time of delivery followed by a distribution of the profits at certain intervals. The produce thus delivered is classified and graded at the headquarters of the association, and the initial payment is made on the basis of this classification. For the purpose of marketing, the produce is "pooled." These principles—contracts, commodity organization and pooling—form the basis upon which a great part of Danish

co-operative marketing is conducted, and have been widely copied in America, Canada, Australia and elsewhere

The benefits which agriculture has derived from the European co-operative system are many. By the centralization of purchase and of sale, considerable economies have been effected, not merely in consequence of the elimination of the middleman and of bulk handling of the produce, but by the removal of the powers of exploitation which buyers and sellers of agricultural [illegible] not infrequently exercised over unorganized farmers. In organized marketing, large-scale handling has enabled scientific grading and standardization to be carried out, which in turn has led to the production of standard grades of produce and standard breeds of live stock on the farms This again, as in the case of bacon, has led to a general improvement in the quality of farm produce, and has greatly added to the competitive strength of the central export associations in foreign markets. Their products have earned a reputation for uniformity and sustained high quality against which unorganized farmers have found it increasingly difficult to compete

**Canadian Wheat Pools.**—Canada affords some remarkable examples of the development of large scale co-operative marketing enterprise, of which the wheat organization is the most significant The Saskatchewan Co-operative Elevator Company originated in the widespread discontent which was felt by farmers at the growing powers of the elevator companies.

Alberta followed the lead of Saskatchewan by setting up the Alberta Farmers' Co-operative Elevator Company in 1913, and four years later this company was taken over by the United Grain Growers, Limited. The movement towards centralized marketing has undergone further important developments For the purpose of selling, an organization known as the Saskatchewan Co-operative Wheat Producers, Limited, was formed, with headquarters at Regina. Members of the company, who already form a substantial proportion of the wheat growers in the province, enter into a five years' contract to sell the wheat through the company. Very similar arrangements have been made in Manitoba and Alberta, the respective organizations being the Manitoba Co-operative Wheat Producers, Ltd , with headquarters at Winnipeg, and the Alberta Co-operative Wheat Producers, Ltd., with headquarters at Calgary. To complete the system of centralization only one step remained, namely, to unite the three provincial pools into one organization. This step was taken. The Canadian Co-operative Wheat Producers, Ltd., with headquarters at Winnipeg, was formed as the central selling agency for the above three producers' pools, and operated for the first time in respect of the 1924–25 crop. The handling of milk, butter and cheese, the marketing of wool, live stock, poultry and eggs, fruit and other produce by co-operative enterprise has also made considerable advance in Canada since the World War of 1914–18.

**Australian Wheat Pools.**—The co-operative wheat pools of Australia are an example of a somewhat different character, since they came into being as the result of direct State action in order to meet the abnormal conditions during the War. They have brought about a fundamental change in the system of marketing wheat in that country. The original scheme was compulsory. It was entered into by the Governments of the Commonwealth, the States of New South Wales, Victoria, South Australia and Western Australia for the purpose of realizing to the best advantage the wheat harvests of the respective States, and for making advances to farmers pending the realization. The scheme was first applied to the 1915–16 crop, and it was subsequently decided to deal with the succeeding crops on the same principle. The duty of realizing the crop was placed in the hands of the Australian Wheat Board, consisting of ministerial representatives of the Governments of the Commonwealth and the respective States, and one representative of the growers from each State.

In each State a local board or commission controlled the operations of the scheme within its area, and the local board effected all local sales, including sales to millers Under arrangements with the Australian banks made by the Commonwealth and State Governments, advances were made to farmers upon delivery of their wheat at railway stations to the appointed representatives The proceeds of the wheat sales were applied, as realized, in reduction of the bank over-drafts which had been used for the payment of advances and expenses In 1922 the compulsory pooling of wheat was abandoned, but the principle of pooling the exportable surplus was continued on a voluntary basis under the respective State Governments Under this scheme, as in the case of the compulsory scheme, each State ultimately received, in respect of the grain actually shipped, the average net profit from the overseas realizations, which, after paying expenses, was distributed *pro rata* amongst the growers.

Mention must also be made of the rapid growth of agricultural co-operation in India, which has mainly taken place during the present century. Indian co-operation bears a much closer resemblance to European than to the American or Australian systems As in Germany, it has been developed largely to provide credit (and insurance) facilities, and to a limited extent for the purchase of requisites and the sale of produce. (X.)

## THE UNITED STATES

For more than half a century farmers of the United States have been actively interested in the co-operative way of doing business. As early as 1870 and in isolated cases even before that, farmers in this country were banding themselves together into local groups and were marketing farm products, purchasing farm supplies, and providing themselves with farm business services on a co-operative basis. The first broad expansion in the development of co-operative organization in this country occurred under the stimulus of the Granger movement, which reached the peak of its activity during the early '70s Later, further stimulus was given to the movement by other farm organizations such as the Farmers' Educational and Co-operative Union, the Farmers' Alliance, the American Society of Equity, and more recently, of course, by the American Farm Bureau But, generally speaking, agricultural co-operation as it has developed in this country represents a movement separate and distinct from the general farm organizations. It is wholly an economic movement concerning itself primarily with the marketing of farm products, the purchasing of farm supplies and the providing of farm business services on a co-operative basis.

During its early years the movement was beset by many failures of the local associations, chiefly because of the [illegible] practices. Much has been done to correct these weaknesses Sounder business practices have been adopted and operating policies have been changed from time to time to meet changing economic conditions. The co-operative principles, however, remain much the same today as they were 50 years [illegible] democratic control, limited returns on capital, and distribution of savings on a patronage basis still remain the dominant features of co-operative activity in this country. Agricultural co-operation in the United States has made its greatest gain since 1915. No other period of similar length in the history of the movement has given rise to as many associations as were formed during the years 1915 to 1921. In 1921 more than 12,000 associations, scattered throughout the United States, were in operation Since that time, the number of active associations has declined slightly, but with a definite trend toward the formation of large-scale associations operating on a State-wide or regional basis, membership and volume of business has continued to expand. In 1939, almost 11,000 associations reported an aggregate membership of 3,300,000 and a grand total business of $2,100,000,000.

In the United States, co-operatives have developed largely along commodity lines and the status of the movement can best be described by treating it in this manner.

Dairy Products.—In volume of business and in number of members, dairy co-operatives lead all other commodity groups. Scattered throughout 45 States are more than 2,400 dairy co-operative organizations selling milk, cream, butter, cheese and other dairy products for almost 750,000 farmers. Approximately 48% of all the fluid milk, 39% of all the butter, 25% of all the cheese and lesser amounts of other dairy products pass through the control of co-operative marketing organizations at one stage or another as these products move from farm to consumer.

**Livestock.**—The co-operative livestock marketing associations may be divided roughly into two groups: (1) those operating primarily at terminal markets, and (2) those operating primarily at country points. The first group is composed of 43 large terminal sales associations with 12 branches operating on 42 of the larger markets in the United States. This group of associations handles about one-fifth of all the livestock sold at public stockyards The latter group is composed chiefly of local associations engaged primarily in assembling and shipping. In 1940 there were about 850 associations of this type in operation. A few of the local associations do their own selling, but the large majority of them consign the livestock to commission associations on the terminal markets.

**Grain.**—Co-operative grain handling facilities, which vary from inexpensive portable elevators to million-bushel terminals, are to be found in nearly every section of the nation where grain is produced on a commercial scale. These facilities are the property of more than

2,600 grain co-operatives which in turn are owned by 360,000 farmers. The typical local elevator has a membership of 100 to 200 persons, each of whom owns one or more shares of stock in the organization. Grain is received from both members and non-members and generally the prevailing price is paid at the time of delivery. Likewise, farm supplies such as feed, fertilizer, coal and machinery are sold at "going" prices. Any earnings or savings made by the association are later distributed as patronage dividends on the basis of the volume of business transacted. Many of the local elevators hold membership in large regional sales agencies through which much of the grain is marketed.

**Fruits and Vegetables.**—In all of the important commercial growing areas, producers of fruits and vegetables have developed co-operative marketing associations. More than 1,100 associations located in 45 states are now (1940) in operation. The greatest development has occurred in producing areas farthest from the large eastern markets. California, Florida, Colorado, Oregon and Washington are the leading states. Approximately 60% of all the citrus produced in this country is marketed by co-operative organizations. More than 180 associations, scattered over 33 states, are marketing potatoes. Apples coming mainly from the Pacific northwest, the Shenandoah valley, and the commercial areas of Michigan and New York, are handled by 78 associations. Strawberries from Louisiana, Missouri, Arkansas, Kentucky, Virginia and other commercial areas are placed on the market by 125 co-operative associations. Many other fruits and vegetables are handled in substantial volume by co-operative organizations. Some of the more important of these are grapes, prunes, peaches, pears, beans, celery, tomatoes, lettuce and asparagus.

**Cotton.**—Co-operation among cotton farmers in this country has developed along three distinct lines: (1) cotton marketing associations, (2) cotton gins and (3) cottonseed oil mills. Fifteen large-scale centralized marketing associations, most of which are operating on a state-wide or regional basis, report an aggregate membership of 280,000 cotton farmers, and during recent years have handled from 1,500,000 to 2,000,000 bales of cotton annually. The cotton gin movement has reached its greatest development in Texas and Oklahoma where 20% to 25% of the crop is ginned through farmer-owned and farmer-operated plants. The movement is gradually spreading to other cotton states and at least a few co-operative gins will be found in Mississippi, New Mexico, Arizona, California, Louisiana and Alabama. Newest of the cotton co-operative enterprises are the cotton-seed oil mills. By 1940 there were six in operation. The first of these was organized in 1922 and has operated continuously since that time. Of the other five, two were organized in 1934, two in 1937, and one in 1939.

**Wool.**—Approximately 50,000 farmers and ranchmen, scattered throughout the United States, are marketing wool co-operatively. The greater part of the wool marketed co-operatively is handled by 25 to 30 large-scale centralized associations which operate on a state-wide or regional basis. These co-operatives assemble, grade, warehouse and sell the wool for their members. Much of the wool handled by this group of associations is marketed through the office of the National Wool Marketing Corporation of Boston. The remainder of the associations are mostly local wool pools. Generally these organizations are small and often serve but a single county. In most cases they are informally organized and frequently are inactive except for a month or two at shearing time The wool is assembled and sometimes is offered for sale to the highest bidder, sometimes consigned to another co-operative, and sometimes sold direct to the mills.

**Poultry Products.**—The principal business of some 200 associations is that of marketing eggs and poultry for 100,000 farmers. In addition to these 200 associations, approximately some 700 other co-operatives are handling poultry products as sideline enterprises. Chief among these are a number of local co-operative creameries located, for the most part, in the middle western states. In the far western states of California, Oregon, Washington, Idaho and Utah where intensive commercial poultry production has developed on a large scale, poultrymen now own and operate some of the world's largest egg, poultry and turkey marketing associations. At least eight associations located in this area transact an annual volume of business in excess of $1,000,000 each. In the eastern states, where producing areas lie within easy reach of large consuming centres, the auction method of selling eggs and poultry has become very popular. In this area 26 egg and poultry auctions are now in operation. All of these have been organized since 1930.

**Other Farm Products.**—More than 15,000 farmers located mainly in California, Oregon, Georgia and Virginia are marketing nuts co-operatively. Eleven associations with a combined membership of 70,000 are marketing tobacco. Marketing hay is the principal enterprise of eight associations and a secondary enterprise for at least 40 others. There are 25 to 30 sugar beet bargaining associations. In the southern states there are eight or ten co-operatives manufacturing cane sugar. And one or more associations are handling each of the following products: maple sugar and maple syrup, honey, nursery stock, pulpwood, tung oil, broomcorn and fox fur.

**Farm Supplies.**—One of the outstanding developments in the field of agricultural co-operation since 1920 has been the rapid growth of purchasing associations From less than 1,000 associations in 1920, the number had increased to 2,600 in 1939. Volume of business increased from $50,000,000 to $335,000,000 during the same period. Membership has grown to almost 2,000,000 Many of the marketing associations handle farm supplies as a side line activity. Some of the fruit and vegetable associations supply their members with fertilizer, spray materials and packing supplies. Some of the dairy associations handle separators, milk pails, strainers and milk cooling equipment. Grain elevators quite generally handle feed, coal, salt, twine, hardware and other supplies for the convenience of their member-patrons

**Mutual Insurance.**—Farmers' mutual insurance companies, the first of which was organized more than 100 years ago, represent one of the oldest forms of co-operative activity in this country The primary purpose of this type of rural co-operative is to provide insurance on a cost basis. The 1,900 companies now active report an aggregate membership of 3,263,224 and a total of more than $11,000,000,000 of insurance in force.

**Mutual Irrigation.**—Located mainly in the western states are approximately 2,500 mutual irrigation companies. These are voluntary associations of persons engaged in producing farm products under irrigation. These mutual companies differ from the commercial companies in that they are operating on a non-profit basis, they differ from the irrigation districts in that membership and financial support are generally voluntary.

**Mutual Telephone Companies.**—Farmers' mutual telephone companies are now operating in every state in the union. Some 2,000 of these represent fairly large formally organized companies operating complete telephone systems including a switchboard. More than 30,000 others represent small informally organized groups of farm people who have pooled their efforts and constructed neighbourhood lines In many instances, these co-operatively operated lines provide the only telephone service available in the community and if it were not for them these communities would be entirely without telephone communication.

**Rural Electric Co-operatives.**—Among the newer undertakings by co-operatives is that of bringing electric power to rural communities. Since the Rural Electrification Administration was created in 1935, the number of farms in the United States provided with electricity has more than doubled. Much of this has been accomplished through the co-operative form of organization.

**AGRICULTURAL CREDIT.** The credit needed in agriculture is of two kinds. The first is long term credit, required to facilitate land purchase or the execution of improvements; the second is short term or personal credit, required to finance the growing, harvesting or marketing of crops, etc. Systems of agricultural credit as they exist today in various parts of the world may be roughly distinguished according to whether they are based on a co-operative principle or not. Co-operative credit has been successfully developed in Europe (with the marked exception of Great Britain) and in India. In most of the newer countries co-operative systems have been relatively unsuccessful, and other means of financing agriculture have had to be found.

**Great Britain.**—There are very few British institutions specifically engaged in providing credit for agriculture, the bulk of farm credit being furnished by the joint stock banks and tradespeople, insurance companies and private mortgages. In regard to long term credit, two institutions (the Farmers' Land Purchase company and the Lands Improvement company) have, however, sought to specialize in this business. The former has aimed at lending money on mortgage for land purchase, but its operations have been on a very restricted scale. The latter, founded in 1858 and operating under special acts of parliament, has lent upward of £13,000,000 for the purpose of carrying out certain types of land improvement. Apart from these, farmers and landowners have mainly had to rely for long term loans on bank overdrafts secured by the deposit of title deeds and private mortgages. In regard to short term credit, for several years prior to World

War I attempts were made to establish co-operative credit societies in Great Britain on the Raiffeisen model (which had had such widespread success in Germany and other continental countries). In 1910 there were 31 co-operative credit societies in Great Britain with 663 members; during and after this war there was a substantial decline in their number and membership.

In 1922 the subject of credit was considered by a committee appointed by the minister of agriculture, and its report was published early in 1923. Its recommendations were adopted by the government, and the Agricultural Credits act 1923 was passed in July of that year. The objects of this measure were: (1) to enable persons who bought their holdings during the currency of the Corn Production acts (April 5, 1917 to June 27, 1921) when prices were exceptionally high, to obtain mortgage loans from the state repayable within a maximum period of 60 years; (2) to establish co-operative credit societies with powers to borrow from the state. The latter were based on limited liability, each member being entitled to hold any number of £1 shares upon which 5s. had been paid up, and to borrow in proportion to his share holding. The credit societies could borrow from the state £1 for each share so held.

Under the first of the above provisions, mortgage loans were granted to the gross value of £5,000,000. Very little interest was, however, taken by farmers in the formation of co-operative credit societies, only nine societies being actually registered under the act, of which four never commenced operations. In view of the small response to this measure, state advances to credit societies were discontinued in March 1927. Subsequently, the government stated its intention of introducing a bill dealing with this subject.

**Germany.**—Germany may be regarded as the birthplace of co-operative credit in Europe. The typical organizations have been the Landschaften or credit unions (for long term credit) and the Raiffeisen banks (for short term credit). The former originated as far back as 1770, and gradually extended not only in Germany, but to Denmark, Hungary, Russia, Poland, Norway and elsewhere. The basic principle was the issue by the Landschaft of bonds based on estates mortgaged in its favour—the bonds being secured upon the collective guarantee of the members of the Landschaft. The borrower was paid not in cash but in bonds which he could realize on the market. He had the right to repay by annuity or by special instalments, or to cancel the loan by purchasing and tendering bonds. Landschaften bonds were regarded as first-class securities, and during the period 1910–14 were quoted on nearly equal terms with the loan bonds of the empire. The principle of the Raiffeisen banks, which were empowered both to make loans and to take deposits, was originally that loans were secured by the collective unlimited liability of all the members. Limited liability was, at a later date, adopted by a small number of these societies. In some cases they added to their credit business that of purchasing supplies for the members, such as seeds, fertilizers, coal, etc. Under Raiffeisen's personal guidance the local credit societies were affiliated to central loan banks, which subsequently received assistance from the state. The wonderful growth of these societies into a vast banking organization, without incurring any serious losses, is perhaps without parallel in the history of finance. In 1924, out of 38,000 registered agricultural co-operative societies in Germany over 19,500 were rural banks.

The postwar inflation in Germany, involved the whole credit organization in acute difficulties, and with the collapse of the paper mark, confidence was destroyed and depositors ceased to lend their money. For these reasons German agriculture found itself faced with an extreme shortage of capital, interest rates rose to a very high figure and farm mortgages became, for a period, unobtainable. After the stabilization of the currency and the introduction of the rentenmark, drastic reorganization of the credit machinery became necessary. A central institution of agricultural credit, the Rentenbank-Kreditanstalt, an offshoot of the Rentenbank, was established, which operated through the previously existing credit institutions Ultimately, with the aid of loans raised in the United States, the situation was considerably relieved and rates of interest substantially reduced.

**France.**—The conspicuous feature of agricultural credit in France is the state subsidy which it carries with it. Under the Méline act of 1894 all or part of the members of one or more agricultural *syndicat* could constitute a credit society, whose capital was obtained by subscription of members. The credit society became a *filiale* of the *syndicat*. A considerable growth of these societies took place with the assistance of a voluntary organization which prepared model rules. In 1897 it was made a condition of the renewal of the charter of the Bank of France that it would place at the disposal of the state without interest 40,000,000 francs, together with an annual share in the profits of the bank, for the assistance of agricultural credit. In 1899 regional banks were created, the members of which were the local credit societies, and the above subsidy enabled the regional banks to reduce their rate of interest to the credit societies, and consequently to provide cheap credit to farmers. The number of regional banks in 1921 was 69, with nearly 5,000 credit societies affiliated to them. The extension of the system to the provision of long term credit was made under acts of 1910 and 1920, which permit a maximum loan of 40,000 francs to individuals to facilitate the acquisition and management of rural properties.

**Canada.**—In Canada credit unions have been more successful, and over 150 with a membership of more than 66,000 have been organized since 1906, mainly in Quebec and neighbouring provinces. By a number of acts the provinces of Canada have also sought to extend the facilities for short term credit to farmers. These include the Livestock Encouragement act, 1917, of Alberta, under which persons may form an association and jointly apply to the Livestock Commissioners for a loan; the Livestock Purchase and Sale act, 1913, of Saskatchewan; the Rural Credits act, 1917, of Manitoba, and a similar act in Alberta, both designed to promote co-operative credit. Mention should also be made of the Ontario Farm Loan act and the Agricultural Development act passed by the Ontario Legislature in 1921—designed both to assist land settlement and to provide short term loans. As regards long term credit, legislation has been enacted by the separate provinces. Manitoba passed Manitoba Farm Loan act, which became effective in 1917, and was subsequently amended in 1919 and 1921. The act established the Manitoba Farm Loans association, which serves as the lending agency between the provincial government and the farmers, and is governed by a board of five members including a Commissioner of Farm Loans. Loans are secured upon first mortgages on farm lands and are repayable by annual instalments in 30 years. Saskatchewan has passed legislation on similar lines (the Saskatchewan Farm Loan act, 1917), and Alberta has followed the general lines of the Farm Loan act in the United States.

**Australasia.**—The development of agricultural credit has received and is still receiving a considerable amount of attention in Australia and New Zealand. In most states of Australia state credit institutions, such as state savings banks, make a specialty of providing agricultural credit. A number of acts have been passed in recent years dealing with the subject of rural credit, among which mention should be made of the Commonwealth Bank (Rural Credits) act 1925 making provision for financing producers' organizations in marketing their produce. An account of these measures is to be found in the Australian Year Book 1925. In New Zealand a Royal Commission on rural credit published a report in 1926 which was followed by two acts of parliament, the Rural Advances act 1926 and the Bank of New Zealand act 1926, both designed to assist the development of long term agricultural credit.

**India.**—The development of agricultural credit in India has mainly followed the European model, and has made consistently steady progress. The first act legalizing co-operative credit societies was passed in 1904. This act was replaced by an act in 1912 which closely followed the English Friendly Societies act and permitted other forms of co-operation. The number of rural credit societies under this act exceeds 40,000 and these are mainly modelled on the Raiffeisen plan.

## THE UNITED STATES

The past hundred years have seen a continuously increasing need in the United States for credit to finance farm operations, including the purchase and improvement of farm land and the production and marketing of crops and livestock. The increased cost of farm land, the use of commercial fertilizer, power machinery, and many other factors have contributed to increased credit needs. As a result a large percentage of farmers use credit. Farmers frequently have to go in debt to get in the farming business, either to buy equipment or land. To become landowners, most farmers have to supplement their savings with borrowed capital. The majority of farmers do not have sufficient working capital to supply their needs at all seasons of the year.

Rural credit, during the years in which farmers' credit needs were expanding, did not keep pace with the demand. Interest rates in some sections were abnormally high. At the turn of the century farm organizations and others interested themselves in the problem. Commissions were sent to Europe to study the farm mortgage systems in operation there. Finally, the congress of the U.S. passed the Federal Farm Loan Act of 1916, which provided for the establishment of a farm mortgage credit system. In 1923 provision was made for a system of federal intermediate credit banks which are wholesale credit agencies discounting agricultural paper. Ten years later, the Farm Credit administration was organized bringing together these and other federally sponsored credit services under one supervising federal agency. The Farm Credit Act of 1933 provided for a system of production credit, supervised by the Farm Credit administration, with local associations making loans directly to farmers and obtaining loan funds through the federal intermediate credit banks. This act also authorized the establishment of 13 banks for co-operatives under the Farm Credit administration to make loans to farmers' marketing, purchasing and business service associations. The Farm Security administration, the Rural Electrification administration and the Commodity Credit corporation also are sources of credit for farmers and farmers' co-operatives. Three states have operated rural credit systems but these were (1940) in liquidation. A number of states invest school and other funds in farm mortgages. The rural credit system thus includes commercial and private agencies, such as commercial and savings banks, insurance companies and individuals, supplemented with government-owned institutions and government-supervised co-operative institutions.

**Long-term Credit.**—Farm mortgage credit for purchasing farm land and making permanent improvements is used in much larger amounts but by a smaller number of farmers than credit for short-term production needs. The mortgage indebtedness of farmers in the U.S. was $3,200,000,000 in 1910. It increased during and following World War I to a peak of $10,800,000,000 in 1923. After 1923 it declined year by year to $6,400,000,000 in Jan. 1943. In 1940, 52% of the total was on farms in the 12 north-central states

The relative importance of different sources varies among the various regions. In 1943 important sources were the 12 federal land banks, $1,603,000,000; life insurance companies, $891,000,000; the land bank commissioner, $512,000,000; insured commercial banks, $471,000,000; Farm Security administration, $164,000,000. A large part of the balance was held by individuals.

An outstanding change in farm mortgage credit in the 10-year period, 1928–38, was the shift in sources of credit. The refinancing activities of the federal land banks and land bank commissioner resulted in large increases in outstanding loans of these agencies. On June 30, 1939. these two sources accounted for 37.4% of the farm mortgage debt of the country. Investment of life insurance companies in farm mortgages dropped from 22.9% of the total farm mortgage debt to 12.4% over the 10-year period, 1928–38 Joint stock land banks in 1928 holding 7% of the farm mortgage debt had liquidated their holdings to 1.1% on June 30, 1939.

**The Federal Land Bank System.**—Funds for farm mortgage loans were formerly brought into farming areas largely through banks. Selling farm mortgage notes in their original form became the usual practice. It was generally necessary to find a borrower who wanted a mortgage of a given amount, covering a certain period, and with definite terms. A system was needed which could standardize farm mortgages and hold them as collateral against which bonds could be marketed. The federal land bank system was established by the Federal Farm Loan Act of 1916 to meet these needs. The joint stock land banks, also established by this act and in 1928 holding a peak of $667,000,000 in farm mortgage loans, were placed in liquidation by the Emergency Farm Mortgage Act of 1933. The 12 federal land banks operated under the supervision of the Federal Farm Loan board until 1933, when the board was abolished and the banks placed under the supervision of the newly organized Farm Credit administration. The 12 federal land banks make long-term farm mortgage loans largely through national farm loan associations, local co-operatives, organized in the first instance by 10 or more farmers desiring loans totalling at least $20,000. In 1928 there were 4,500 to 5,000 national farm loan associations in the U.S. Consolidation of associations has resulted in a decrease in number to 3,484 active on Dec. 31, 1942. Each borrower subscribes to stock in the national farm loan association equal to 5% of his loan. The association subscribes to federal land bank stock. The 12 banks had a paid-in capital of $217,506,258 on Dec. 31, 1942. Of this amount, national farm loan associations owned $97,365,018, or 45%, and the U.S. government, $117,176,065, or 54%. About $3,000,000 was owned by direct borrowers.

Federal land bank loans can be made only to farmers or prospective farmers. No land bank loan may exceed 50% of the appraised normal value of the land plus 20% of the appraised value of the permanent insured improvements on the land. The maximum amount loanable is $50,000. The term may extend up to thirty-odd years. All loans are made on an amortized basis. Prepayment privileges are allowed after five years. Borrowers may deposit money in good years to meet instalments in bad years. Funds for making loans are obtained by the sale of long-term bonds. The 12 banks are jointly and severally liable for the payment of principal and interest on all bonds issued. The bonds are not guaranteed by the U.S. government. The interest rate on new loans may not exceed by more than 1% the rate borne by the last bonds issued. The contract rate on loans through national farm loan associations on Mar. 1, 1944 was 4%. This rate has been in effect from 1935. From 1917 through Dec. 31, 1943, the federal land banks made loans totalling $3,376,000,000. Federal land bank loans outstanding on Dec. 31, 1943, totalled $1,358,000,000.

**Land Bank Commissioner Loans.**—As a result of the collapse in farm prices, farm income and land values, thousands of farmers from 1932–35 were faced with foreclosure. Emergency measures were necessary. The Emergency Farm Mortgage Act of May 12, 1933, authorized the land bank commissioner of the Farm Credit administration to make farm mortgage loans of a more or less emergency character. These loans may be made up to 75% of the value of the mortgaged property but cannot exceed $7,500 to one individual. Funds for making loans are obtained through a government-capitalized institution, the Federal Farm Mortgage corporation, which issued government-guaranteed bonds aggregating $1,651,559,000 from its establishment in 1934 to June 30, 1939. Part of these funds were used to purchase federal land bank bonds. As the law stood (May 1946) the authority of the commissioner to make loans expired on July 1, 1946. From Aug. 23, 1933, the federal land banks have acted as agents in making and handling these loans. Some 613,000 commissioner loans, totalling $1,127,662,036, had been made to Dec. 31, 1943. Although a large percentage of loans were used for refinancing purposes, many young farmers have used these funds to supplement federal land bank loans for the purchase of farms.

The Farm Security administration makes first mortgage loans to enable a limited number of competent tenants, sharecroppers and farm labourers, unable to obtain credit elsewhere, to purchase family-size farms of their own and to make needed improvements on those farms. Loans may cover 100% of the appraised value of properties acquired but may not exceed $12,000. The rate of interest is 3%. Annual payments of interest and principal are 4.3%. To July 1, 1943, loans made aggregated $188,000,000. The Federal Housing administration is authorized to insure loans made to buy and improve farms or to modernize farmhouses and other buildings. Fifteen per cent of the amount of a loan must be used for materials and labour for new construction or repairs.

**Terms and Conditions of Farm Mortgage Loans.**—Marked changes have occurred in the terms and conditions of farm mortgages from 1917 when the 12 federal land banks first introduced the amortization principle into farm mortgage lending in the U.S. Prior to this, loans were made ordinarily for periods from five to ten years. As farmers were often unable to accumulate enough money to pay off a mortgage in that length of time the loan was usually renewed, entailing considerable expense. Following the lead of the federal land banks, most insurance companies and some commercial banks are making loans covering longer periods and often repayable on an amortized basis.

The trend in interest rates on farm mortgage loans was upward from 1917 to 1921, and then gradually downward from the early 1920s, except for a short period around 1930. Farmers in most sections were (1944) obtaining farm mortgage credit at the lowest rates ever available in the U.S. Federal land banks were making loans at a contract interest rate of 4%. The interest on instalments coming due prior to July 1, 1944, was payable at 3½%. Land bank commissioner loans were made at 5%, with all interest instalments maturing before July 1, 1944, payable at 3½%. The U.S. government reimburses the banks and the Federal Farm Mortgage corporation for the difference between the contract rate and the temporarily reduced rate. Interest rates of some commercial banks and insurance companies compare favourably with these rates in territories where they make most of their loans.

**Short-term Credit.**—It is estimated that from 60% to 80% of the farmers in the U.S. use some form of short-term credit each year. The largest source of production credit is commercial banks, which on June 30, 1943, had short-term agricultural loans outstanding totalling $1,316,385,000. Most country banks are either directly or indirectly affiliated with the Federal Reserve banks, which makes it possible for them to obtain short-term loans or rediscount eligible notes. Their loan rates vary from 5% to 10%. Credit advanced by merchants and dealers in farm products is usually much more expensive. Many farmers' co-operative buying and selling associations grant some credit to their members. Production credit associations with loans outstanding on June 30, 1943, totalling $256,991,000 are an increasingly important source of production credit. Since 1933, some 530 production credit associations have made production loans to farmers and livestock men. Twelve production credit corporations, one in each farm credit district, helped to organize, capitalized in part, and now supervise the local associations. Funds for making loans are obtained by discounting farmers' notes with the federal intermediate credit banks.

Each farmer-borrower owns class "B" stock in the production credit association equal to 5% of his loan. The capital stock of the production credit associations on Dec. 30, 1942, was $104,246,194, of which $21,989,942, or 21.1%, represented class "B," voting stock owned by 265.749 farmer-members of the associations and $82,256,252, or 78.9%, was class "A," non-voting stock held by the corporations, farmers and other private investors.

From Feb. 24, 1939 to March 1944, the rate of interest charged on production credit association loans had been 4½%. Prior to that date it was 5% but a reduction in the Federal Interstate Credit bank discount rate on the date specified enabled the associations to lower their rate.

Most loans are made on a budget basis. That is, a farmer arranges for his credit for a season and the money is advanced as he needs it. He repays the loan when the crops and livestock financed are sold. Interest is charged only for the time a farmer has the money.

In making production credit association loans careful consideration is given to farming plans and the ability of a farmer to repay a loan from the sale of farm products, rather than basing the loan entirely on the value of the collateral.

Another source of agricultural credit in a few localities is credit unions.

At times many farmers are unable to qualify for loans from banks and production credit associations. To meet the needs of this group, the United States government has provided emergency loans from appropriated funds or those advanced by government corporations. Under this heading may be grouped emergency crop and feed loans; loans made by the Regional Agricultural Credit corporations, and rehabilitation loans of the Farm Security administration. There were outstanding on Dec. 31, 1943, $107,600,000 of "emergency crop loans"; $40,000,000 of "drought relief loans" made in 1934–35, and $12,100,000 of "orchard rehabilitation loans." The Regional Agricultural Credit corporation was very active in 1932–33 and was revived to make emergency loans in 1943. Outstanding loans, amounting to $144,600,000 at the end of 1934, were down to $4,000,000 in 1942, but increased to $32,000,000 at the end of 1943. The Farm Security administration, developed from various relief activities among farmers in the middle 1930s, carries on a program with low-income farmers. On July 1, 1943, outstanding rehabilitation loans amounted to $380,300,000.

**Federal Intermediate Credit System.**—The 12 federal intermediate credit banks were established in 1923 under the Agricultural Credits act as wholesale credit institutions for agriculture, to provide production and marketing credit for periods longer than those ordinarily supplied by commercial banks. In 1933 these banks were placed under the Farm Credit administration and form one of the permanent units in each of 12 Farm Credit districts. The government had paid-in capital (Dec. 1942) in the 12 banks totalling $60,000,000, and they had accumulated earned surpluses of $20,400,000. Funds to lend are obtained largely from the sale of collateral trust debentures. These are not guaranteed as to either interest or principal by the U.S. government, but have been readily salable at low rates of interest.

These banks under the law are authorized to discount paper of any production credit association, bank for co-operatives, national bank, state bank, trust company, agricultural credit corporation, incorporated livestock loan company, savings institution, co-operative bank, credit union, or farmers' co-operative. Production credit associations accounted for about 75% of the loans and discounts of the intermediate credit banks in 1939. Loans to farmers' co-operatives through the Farm Credit system are handled largely by the 12 banks for co-operatives which use the facilities of the federal intermediate credit banks in obtaining part of their loan funds.

**Farmers' Co-operatives.**—The farmers' co-operative movement in the United States has shown large growth in the past 50 years. In 1937 a national survey gave the business of some 10,500 farmers' marketing and purchasing associations as exceeding $2,000,000,000 in a year. The capital of these associations is provided by farmer-member subscriptions and retains from the net proceeds of the products handled. Additional capital is often needed to supplement the association's funds in peak operating periods or to construct plants and to buy equipment.

To supply additional capital, farmers' co-operatives have a number of sources of credit. Commercial banks furnish a considerable portion of their credit needs. Beginning in 1923 the federal intermediate credit banks made loans to farmers' marketing and purchasing co-operatives on the security of commodities in storage. Since 1933 loans to co-operatives through the Farm Credit system have been handled largely by the banks for co-operatives which obtain part of their loan funds from the federal intermediate credit banks. The Agricultural Marketing Act Revolving fund, administered by the Federal Farm board from 1929 to 1933, provided funds for effective merchandising, facility, and commodity loans to farmers' marketing associations. Loans

from this fund were curtailed when the banks for co-operatives were established in 1933.

The 13 banks for co-operatives, one in each of the 12 Farm Credit districts and a central bank in Washington, D.C., make facility, operating capital and commodity loans to farmers' marketing and purchasing associations and to mutual companies. About 30% of the borrowings of marketing and purchasing associations outstanding at the peak period in 1936, according to the national survey, came from the banks for co-operatives.

The Commodity Credit corporation, organized Oct. 17, 1933, by executive order, provides funds for producers and farmers' co-operatives to finance the carrying and orderly marketing of certain agricultural commodities recommended by the secretary of agriculture and approved by the president. Loans authorized at a fixed rate per unit on basic commodities, such as cotton, corn, wheat or wool, may be obtained by producers through banks or other lending agencies on forms provided by the Commodity Credit corporation. The corporation also makes direct loans. Loans of the corporation outstanding on July 1, 1943, excluding loans held by banks and other financing institutions, totalled $218,535,000. The Rural Electrification administration provides funds to co-operative associations of users for financing the construction and operation of rural electric systems. On July 1, 1943, such loans amounted to $327,588,000.

**AGRICULTURAL ECONOMICS.** Agricultural economics is the science which treats of the conditions, laws and institutions that affect the wealth-getting and wealth-using activities of farmers as individuals and of agriculture as an industry. Thus, it is concerned not only with the economic problems of the individual farmer in producing and marketing his products, and in financing his operations, but also with the economic aspects of the political, legal and other social relationships of farm people among themselves and with the rest of society, including the community, state and nation.

The scope of agricultural economics ranges, for example, from the acquisition, organization and use of the means of production on the individual farm to the broad programs and policies which affect the balance of all interests in the production, consumption and conservation aspects of agriculture. It includes, in addition, the study of the characteristics, behaviour and control of agricultural prices, the elements of cost in agricultural production, the problems of agricultural marketing, the methods of financing all phases of agriculture, the social and economic problems inherent in the ownership and use of agricultural land, the geography of agricultural production, and finally, the welfare of farm people as conditioned and determined by the foregoing aspects and by the size and distribution of farm population as related to agricultural opportunities.

Two methods of study have been used by workers in this field. The primary method has been to collect basic data regarding farmers, farms and institutions that serve rural people as well as more general economic data concerning agricultural subjects. As a part of this method, various research techniques have been applied to the data to ascertain those general principles which underlie the economy of rural people and institutions. A second method of approach has been to select from currently accepted principles of economics those considered helpful in the analysis of the problems under study. The two approaches, of course, have never been entirely separated and as the work has developed they have come to be more and more combined. Some studies have been confined to problems such as the economic organization of farms and of markets, while others have dealt broadly with issues involved in community, state, national and international policies which affect farmers, consumers or even entire populations.

The emphasis upon agricultural economics as a special phase of economics is based on man's dependence upon the products of the soil to meet his primary needs, especially for food, clothing and shelter, as well as upon the large number of people who are engaged in the occupation of farming. In fact, the basis of the most pressing problem among people throughout the world is man's relationship to the availability of food and other agricultural materials. Agricultural economic problems have become more acute with the development of commercial agriculture and the growth of the world's population from the beginning of the 18th century. The abundance of food produced in relation to population in some of the newer countries, including those of North and South America, Australia, New Zealand and parts of Africa, gave rise to problems of maintaining a profitable well-balanced agriculture based upon domestic and [illegible]. On the other hand, the pressure of population upon the food supply in densely populated countries, such as India and China, has been responsible for many social conditions peculiar to such countries. Primitive methods in such countries are largely the result of the scarcity of raw materials, land and capital goods, in relation to population. Under either set of conditions, the attainment of a balance between agriculture and the rest of the industry of a country and the development of international trade relationships which will enhance the well-being of the people are complex problems of major importance. Economic problems which have arisen from either a commercial or a subsistence agriculture have resulted in specialized research in agricultural economics.

Agricultural economics as a systematically organized body of knowledge is largely a product of the 20th century. In the United States, for example, following 1850, the invention of labour-saving machinery, improved transportation and communication facilities, and the bringing into cultivation of extensive fertile land areas rapidly expanded production to the point of burdensome surpluses. The amount of wheat production in excess of domestic needs in the U.S. at the end of the 19th century, for example, compared favourably with the total production of any European country. These surpluses, offered upon world markets, helped to disorganize the agriculture in European countries, and led to greater dependence upon the importation of food. With expanded grain production in some countries, improved transportation facilities and deficit food production in other countries, the comparative advantage among different countries led to increased specialization in production and to expanded world trade in agricultural products. The importance of these problems in both surplus and deficit countries naturally drew the attention of trained economists and technically trained agricultural workers interested in economics. It was in this setting that modern agricultural economics came to be recognized as an important agricultural science.

### EARLY CONTRIBUTIONS TO AGRICULTURAL ECONOMIC THINKING

Many references, both secular and religious, point to the importance of agriculture in the economic life of early people. In ancient Greece, knowledge pertaining to religion, ethics, law, economics and philosophy attained a degree of systematic treatment. Aristotle recognized the importance of the so-called art of money-making, and observed that husbandry and stock raising constituted the true and proper art of money-making, with the exchange of goods given a secondary place. Aristotle's recognition of man's dependence upon production, exchange and consumption, stands as one of the early recorded contributions to economic thinking. From the time the division of labour and exchange began to characterize organized society, agriculture has generally been accorded an important place in economic thought.

Some early Roman writers considered the revival and reform of agriculture to be fundamental in preventing the moral corruption of the nation. The economic importance accorded agriculture by the Romans is expressed by Cicero in the statement that "of all means of acquiring gains, nothing is better than agriculture, nothing more productive, nothing more pleasant, nothing

more worthy of a man of a liberal mind" Roman writers, Cato, Columella, Varro and Virgil, paid special attention to technical agriculture and rural economy; they opposed large estates, absenteeism and the spread of slavery, but praised small-scale farming. Pliny lamented that the large estates—latifundia—had brought ruin to Italy.

During the middle ages, 400 to 1300 A.D., much of the land of Europe was cleared and brought into agricultural use. The feudal system tended to provide for local self-sufficiency although goods and services were limited. Some new patterns of land settlement were undertaken, but there was a tendency for the agriculture to develop in similar ways. However systematic the thought of that period may have been, it has not contributed much lasting influence on present-day agriculture Monks and other members of religious orders which were large landholders studied the Roman writers. In the 13th century, Walter of Henley, in England, wrote a number of manuscripts on agriculture, which dominated the field until the 16th century when they were superseded by works on husbandry and surveying, in 1534, credited to John Fitzherbert. The gradual decay of feudalism from the early modern period opened the way for more systematic thinking regarding economic life and well-being

The place accorded agriculture in the economic life of a nation received major consideration at the hands of the French physiocrats under the leadership of Dr. François Quesnay in the 18th century. The physiocrats praised agriculture for bringing into existence a net product (*produit net*) and stated that if the order or laws of nature were followed nature would be found providential in meeting human needs. In fact, they regarded all other industry to be sterile and agriculture as the only new source of wealth, because agriculture was the only industry that produced more than was put into it in the form of labour and capital.

### AGRICULTURAL ECONOMICS IN THE 19TH CENTURY

**Great Britain.**—In the agricultural history of Great Britain, throughout the 19th century, there appeared much of the foundation upon which modern agricultural economics has been developed. In the classical school of economics, David Ricardo and Thomas R. Malthus deserve mention for their contributions of principles related to the economics of agriculture. Malthus took the point of view that nature instead of being munificent was niggardly, in the sense that population tended to outrun the food supply. Instead of looking upon agriculture as producing a net product, his theory was that as the supply of land became limited, man was forced to move to poorer and poorer grades of land. As this expansion in production became necessary, the best land produced a product above the cost in labour and capital required to produce the same amount of product on the poorer grades of land. Thus, he pointed out, in his essay on the *Principle of Population,* published in 1803, that, since population tended to increase by a geometric ratio while agriculture increased only by an arithmetic ratio, eventually population would tend to outrun the food supply. This would force man to operate successively lower grades of land except insofar as checks on population, such as famines and wars, retarded or reversed the trend. It was this theory in particular that gave Malthus and some of his associates the name of the "pessimists." His theory was developed when England was experiencing a shortage of food supplies at home.

Undoubtedly this theory was used by Ricardo in his development of a more complete explanation of rent. Ricardo's theory of rent, in brief, was that, with the growth of population, it became necessary to cultivate land of an inferior quality and that, as labour and capital were added to land in use, a reduced return was received for the added effort, or a diminishing return. Rent of land he regarded to be that share of the product of the soil which the landowner could charge for the use of the "original and indestructible powers of the soil." Land rent to Ricardo, therefore, represented the return from the better grades of land above that obtained from the labour and other costs expended on an equal area of low-grade land which produced just enough to attract labour and to justify the other costs incident to production. The extent of cultivation on the lower grades of land would be determined by the needs for food. He further recognized that the best grade of land would profitably absorb more labour and other costs than an equal area of low-grade land. Thus, Ricardo recognized both the intensive and extensive margins of cultivation. While many criticisms and refinements have been made, the contributions of Malthus and Ricardo, in pointing out the differential return from land of different grades, are fundamental in the economic theory of land rent, although the incorporation of capital in land makes it difficult to determine true economic rent. Among the criticisms should be included those made in the 19th century in the United States by H. C. Carey, F. List and F. A. Walker, and in Germany by J. H. von Thuenen.

The industrial revolution of the 18th century required marked adjustments in agriculture to meet the new conditions. As agriculture took on more of a commercial aspect, Jethro Tull, Charles Townsend, and Robert Bakewell introduced farming innovations which helped to meet the changing agricultural conditions. William Marshall, in his surveys of British agriculture, published in 1785, and Arthur Young, mainly in the next decade, as author and as secretary of the board of agriculture, deserve credit for careful study of agricultural practices and the development of a popular interest in agricultural economic problems. Marshall gave his book the title of *Rural Economy* and covered both agricultural practice and rural life The writings of James Caird, *English Farming in 1850 and 1851,* and R. E. Prothero, *The Pioneers and Progress of English Farming,* in 1888, analyzed the problems of the individual farmer and the relationship of farm profits to the well-being of the landlord and of the nation.

Great Britain, in common with the United States, Germany and other countries, felt the effect of the decline in prices of farm products following the end of the Napoleonic wars in the 19th century. As a result, in 1833, a parliamentary commission was appointed to study agricultural problems. This report found no magic solution for farm problems, but recommended changes in farm practice with special reference to farm leases to permit farmers to depart from specified crop rotations. This focused attention upon the need for adjustments in rent because of the uncertainty of prices, and upon compensation to tenants for unexhausted improvements which they had placed on farms and from which they had not received full benefit before they were required to quit the property. This was intended to induce tenants to improve the properties. Writings dating from 1650 had advocated legislative action respecting landlord-tenant relationships, but the bill introduced in parliament in 1850 entitled, "A Bill for the Improvement of the Relation between Landlord and Tenant in England and Wales," put the issue into clear perspective. An Agricultural Holdings act dealing with the relationships of landlords and tenants was passed in 1883 and was modified at intervals by later acts. This legislative action based upon practical local experience provided arrangements which tended to standardize and develop improved landlord-tenant relationships.

**Germany.**—In Germany, Albrecht Thaer occupied much the same place with respect to agriculture as did Tull, Townsend, Bakewell, Marshall and Young in England. He introduced new practices on his own farm; he published in 1798, a three-volume work on English agriculture, which was followed by further publications dealing with the fundamentals of agriculture. As a result of his work, the king of Prussia induced him to establish an agricultural school and experimental farm near Berlin. His interest was in the economic phases of farming as well as in the physical and biological problems. One of his students, Johann Heinrich von Thuenen, gained recognition for his presentation of economic considerations in determining the crops which farmers should grow under varying conditions of soil, transportation and markets. In *Der Isolierte Staat,* published in 1826, he criticized and refined Ricardo's theory of rent, pointing out that rent resulted because of location and relative transportation costs as well as from gradations in the productivity of land.

By the close of the 19th century, the more important German universities were offering courses in the field of agricultural economics. From the standpoint of emphasis, one could divide the professors of agricultural economics in Germany into two groups:

those who approached the field from a background of political and social economy, and those who were trained primarily in the technical phases of agriculture. An exception was Freiherr von der Goltz at the Agricultural College of Bonn, who included in his instructional work the history of agriculture, farm accounting, the economics of farm management and the political economy of agriculture. Von der Goltz deserves attention for his attempt to round out the field of agricultural economics, treating the economic problems which the farmer meets in his farming operations, as well as those which affect him but are beyond his immediate control.

German thought continued to distinguish between what might be termed farm management (*Betriebslehre*) and agricultural policy (*Agrarpolitik*). The former refers to those economic principles of farm management which lead to maximum net profits from the operation of a farm; while the latter is concerned with providing an opportunity, under the assumed legal and social order, to all persons in agriculture in accordance with their skill and activity, and helping to remove barriers to or to establish procedures for the development of the agricultural industry as a whole. In addition to Von der Goltz and Von Thuenen, credit must be given Wilhelm Roscher, who published a book entitled, *Nationalökonomik des Ackerbaues*, 1854, and in later years to Max Sering for contributing to the basic principles which aided in the development of agricultural economics in the United States.

**United States.**—Economic problems of agriculture received increasing attention in the United States in the period 1880 to 1900. In general, this was a period of falling prices and of a rapidly expanding agriculture. The low purchasing power of farm products had been accentuated by the rapid development of railroads and improvements in farm machinery which led to a rapid increase particularly in the production of wheat, corn, hogs and cattle. This expanded production and resulting low prices coincided with a deflation in the currency. Because of inability to pay debts, and the large number of mortgage foreclosures, farmers sought relief through governmental action.

Attention was attracted to the economic difficulties of agriculture by the Grange and the Farmer's Alliance following 1870, and the efforts of the Populist party in 1892. Of this group, the Grange was most successful in securing legislative and administrative help for agriculture as evidenced by their early sponsorship of the Interstate Commerce commission, free rural postal service, food and dairy product laws and tax reforms which found their way into state and federal legislation.

Interest in agricultural economic problems was shown by the American Economic association in 1892 when it devoted part of its program to the farmer movements in northern states. In 1896, this group discussed questions pertaining to the rapid growth of tenancy, mortgage indebtedness, soil exhaustion through one-crop farming, migration of young people from farms to cities, rural free delivery of mail, extension of electric railroads in the rural districts and better educational facilities for farm people. The general conclusion of the economists at that time was that the solution of the farm problem depended upon suitable adjustments in farm economy by the farmers themselves rather than through government action. The gradual rise in prices during the early part of the 20th century, however, probably did more to improve the prosperity of agriculture than changes in the organization of farms.

In the early part of this period Henry George's book, *Progress and Poverty*, written in 1880, received marked attention although it probably had more effect upon governmental policies in Europe than in the United States.

George developed a theory that landowners held a monopoly because of the growth in population, and were able to demand increased rents which made workers poorer. There is evidence that he accepted the Malthusian theory of population and the Ricardian theory of rent rather literally, and concluded that the way to secure more equitable distribution of income was through the "equal right to the use of land." This he would obtain through taxing the value out of land and using the income from the tax to support all public activities. United States economists in general attacked the single tax on many grounds but George must be credited with sensing the impact upon farmers of the problem of paying for their farms each generation.

Prior to 1900, the major emphasis of the agricultural colleges and experiment stations in the United States was upon the physical and biological problems of agriculture. Some attention, however, was given to the questions of farm tenancy, costs of producing farm products and farmer co-operation in particular (*See* AGRICULTURAL CO-OPERATION.) Thomas F. Hunt, who, in 1892, first offered a course in rural economics at Ohio State university, deserves special mention as a pioneer in the field of agricultural economics. This course, dealing with the historical as well as comparative agriculture, included lectures on Egyptian, Grecian, Roman, British and U.S. agriculture. Part of his course was devoted to practical farm management. His teaching influence was felt directly in the universities of Illinois, Ohio, New York and California. He was also an influential member of the American Association of Agricultural Colleges and Experiment Stations, and had wide influence in the introduction of the teaching of rural economics in the United States. In 1896 the course in rural economics was recommended by the association to be offered in all agricultural colleges while the outline for the course, adopted in 1900, was similar to that of Hunt's book, printed in 1899, entitled *Lectures in the History of Agriculture and Rural Economics*. In pioneering agricultural economic teaching, Hunt saw a place for economists and statisticians in agricultural colleges. While Hunt had much influence upon agricultural economics, because of his personal leadership, I. F. Roberts and F. W. Card came into prominence about the same time because of their contributions to farm management subject matter.

## DEVELOPMENT OF AGRICULTURAL ECONOMICS

**United States, 1900–1919.**—The beginning of the 20th century marks a convenient point from which to describe the development, scope and techniques employed in agricultural economics in the United States.

Teaching of agricultural economics in the state agricultural colleges, indicated by the names of the courses, began prior to 1900 in only eight states. Within the next 20 years practically every state college offered several courses in this field. The organization at these institutions of separate departments or divisions of agricultural economics, called by such names as rural economics, farm economics and farm management, as well as agricultural economics, began in 1904 at Ohio State university and now includes all of the agricultural colleges in all states. In many institutions, rural sociology is included as a division of agricultural economics, while, in some, rural sociology is a separate division of work.

Outside of these colleges, prior to 1920, the work of T. N. Carver, at Harvard, merits special mention. Carver was a trained economist with strong agricultural and sociological interests. Perhaps more than others of that period, he emphasized that all agricultural economic work should have as its goal better living for rural people in proper balance with the rest of society.

Early agricultural economics research in the state agricultural colleges was focused largely upon farm management. In 1902, W. M. Hays and Andrew Boss initiated cost accounting research in Minnesota. With gradual refinement, the work was continued there until temporarily interrupted by World War I. Shortly after 1910, detailed cost accounting studies of the entire farm business were developed especially in Illinois, New York, Ohio and Wisconsin, and later both complete farm cost accounting and enterprise cost studies were conducted in many states (*see* FARM MANAGEMENT).

At Cornell university in 1908, G. F. Warren developed the farm management survey type of study, a survey of the entire farm business. The first study was made of farms in Tompkins county, New York. This method of study was a major contribution to farm management research and became the basis of the method employed in much of the farm management research by the United States department of agriculture.

At Wisconsin some work was being done in cost accounting and farm survey records, but a much broader program was initiated

under the leadership of H. C. Taylor. Publications prior to 1919 reported studies at Wisconsin in farm credit, co-operative marketing, agricultural history, farm tenancy, land economics, prices of farm products and rural life, as well as farm management. In other institutions similar expansion was taking place.

Research in the farm management aspect of agricultural economics under the auspices of the United States department of agriculture virtually dates from 1902, when W J. Spillman became a member of the staff. Under his direction, studies were initiated to determine the way in which the best-paying farms were being managed, the relationships to surrounding conditions such as proximity of markets, the way of leasing or controlling the use of land, and the method of farming followed A separate appropriation for the office of farm management within the bureau of plant industry of the department of agriculture was made effective in 1905 Farmers' bulletins and other publications, prepared under the direction of Spillman, indicate that the work was quite closely restricted to the study of individual farms and farm practices until 1908.

Spillman and his associates contributed to an enlarged interest in studies in agricultural economics although major emphasis was given to farm records and bookkeeping. The work of the office of farm management was closely associated with the early agricultural extension work, which was established in 1914, under the Smith-Lever Extension act. C. B. Smith, who had been associated with Spillman in the office of farm management, became the director of the extension work in the northern and western states. Under him and his associates, the farm management demonstrations, based upon farm management survey records, was spread throughout these states in co-operation with the state extension services working through the county agricultural extension agents Interest in a practical system of farm financial and production records to be kept by farmers was developed in a number of states following 1914, particularly in Illinois, Minnesota, Nebraska and Ohio. Farm records practically displaced farm management surveys in extension work in 1917.

Federal work in agricultural marketing followed a development somewhat parallel to that of farm management and was initiated at about the same time. This led to the establishment of the office of markets in 1913. Especially to be noted among conditions which contributed to marketing problems in the United States were the long distances between centres of production and consumption, and the development of large-scale firms in various branches of the food industry. There was widespread feeling on the part of producers that something was wrong with the system of distribution. Reflected in political demands, it stimulated inquiry, first, by governmental agencies, then, by agricultural experiment station workers. The development of co-operative marketing and processing by farm groups made them more conscious of problems involved in market operations and gave stimulus to research.

In the U.S. department of agriculture, interest in marketing originated from two sources: statisticians and technical production men. The latter initiated commodity studies which laid the foundation for grade standards for various farm commodities. The office of markets, later becoming the bureau of marketing, emphasized systems of grading, standardization and inspection. World War I created interest in market information and a market news system was initiated. The rise in the cost of living developed interest in economic studies in this field and economists were brought into the federal work in marketing

One of the early contributions to the field of agricultural economics was the work done in agricultural statistics, dating back to 1867, when data were first collected on the production and yield of important crops. The names of N. C. Murray and L. M. Estabrook following 1900 are associated with the refinement of the crop and livestock-reporting service and extended the use of questionnaires mailed to farmers for collecting important statistics pertaining to agriculture These data, collected over a long period of time, have provided a basis for useful economic studies of agriculture.

Rapid development in the teaching, research, extension and regulatory phases of agricultural economics followed the organization of the American Farm Management association in 1910. At that time, a paper by K. L Butterfield, entitled "Analysis of Rural Problems," set forth the place of agricultural economics among other agricultural subjects Butterfield, in keeping with much of the thinking of that time, divided agricultural subject matter under five headings, as follows (1) the technical aspect. "farm practices," or "agriculture", (2) the business aspect: "farm administration," or "farm management"; (3) the scientific aspect: "agricultural science"; (4) the industrial aspect: "agricultural economics"; and (5) the community aspect: "rural sociology."

It is probable that the distinction between farm management and agricultural economics emphasized at that time was responsible for the delay in including the subject matter of farm management with that of agricultural economics. While the work of the American Farm Management association went forward steadily, a second group, which early took the name "agricultural economists," was likewise developing. In April 1913 a group of men interested in the broad field of agricultural economics called a conference known as the National Conference on Marketing and Farm Credits, and in 1916 the Association of Agricultural Economists was organized to promote the study and research of the various phases of agricultural economics, including agrarian legislation. In the organization and objectives of both this association and the American Farm Management association, one finds the problems in the field of agricultural economics set forth more clearly than previously. The formation of the American Farm Economic association, in Jan. 1919, marked the unification in the United States of the workers interested in the economics of agriculture.

Appropriations under the Smith-Lever act in 1914 provided federal aid, specifically for extension work in farm management, and paved the way for expanded work covering various economic problems as they became more evident following World War I Extension workers in contact with farmers rapidly became conscious of the varied economic interest of farmers.

In addition to those who have been mentioned in connection with early agricultural economic work, at least another group deserves recognition: C. J. Brand, B. H. Hibbard, E. G. Nourse, L. D. H. Weld, and others, who initiated marketing studies of an economic character and wrote extensively. At the same time, some technically trained agricultural workers initiated commodity studies, emphasizing the development of classes and grades of products together with their physical handling. An example of this is the work of H. W. Mumford and his associates which later became the basis for the federal standards for market classes and grades of livestock and meat.

Much research in marketing was done by private and co-operative business firms, particularly with respect to the demands for their products. One of the early notable books on co-operative marketing was published in 1914 by G. H. Powell, manager of the California Fruit Growers exchange. As a plant pathologist, he began studies of losses of citrus fruit in shipment and reached the conclusion that they could be prevented by improved methods of harvesting and packing. The formation of local co-operatives to perform these operations was an important link in the establishment of the California Fruit Growers exchange as an outstandingly successful co-operative marketing organization (*see* AGRICULTURAL CO-OPERATION).

Work in agricultural geography and history has been based largely upon the federal census of agriculture which first included farm production figures in 1840; acreage and values of farm property in 1850; land tenure data in 1880; farm mortgage data in 1890; and more complete information relative to land tenure, land use and other aspects of farm life from 1900 to date. Population data, from 1790, and occupational classification, since 1820, have been invaluable. The graphic presentation of data in the census volumes, developed first in 1880, has been of value in helping students to obtain fundamental information regarding the geography of and trends in agriculture. F. A. Walker was prominently associated with much of this development. Since 1900, census data

has been used extensively in presenting agricultural information historically and geographically.

Prior to 1920, land economics studies have been conducted at several institutions including the Universities of Wisconsin and Illinois. R. T. Ely, together with his associates at the University of Wisconsin, pioneered in the development of land economics. L. C. Gray for many years was the head of the early work in land economics in the bureau of agricultural economics.

While separate treatment is often given to rural sociology, it is included with agricultural economics in so many institutions and is so closely associated with it that it merits mention here. C. J. Galpin, while at the University of Wisconsin, pioneered in the study of the construction of the rural community in relation to trade centres, schools, churches and other centres of the community activities. The research projects in this field have emphasized the relationship of the individual and rural groups to institutional influences in their effect upon family and community lives.

A brief appraisal of agricultural economics in the United States, from 1900 to 1919, should emphasize the improved techniques of study and the systematic presentation of subject matter. Marked advance was made from abstract discussion and reasoning regarding agricultural problems to the adoption of the research method of analysis. Sound statistical methods and systematic economic interpretation of results led to widespread recognition of agricultural economics as a separate field of work.

It was the broadened interest in the economic problems of agriculture that led to the reorganization of the office of farm management of the United States department of agriculture in 1919. H. C. Taylor then became head of the office of farm management. The reorganization included seven divisions of work, as follows: cost of production, farm organization, farm finance, farm labour, agricultural history and geography, land economics and farm life studies.

**United States, 1919–1943.**—The 15 years after World War I were characterized by a growing demand for governmental action designed to bring relief from the low prices being received for farm products (*see* AGRICULTURE). The adjustment in the use of crop land to obtain food supplies needed during the war, and several years of large crop yields, left the U.S. with surplus grain for peacetime conditions. The postwar tendency was for Europe to develop a self-sufficing agriculture, while the accumulated surpluses in Argentina, Australia and other distant regions added to the available food supply as shipping became available. Farmers found, on the other hand, that new machinery, building materials, household goods, taxes, interest rates and other costs remained at a high level. Inflated land values, through 1920, led to the assumption of heavy mortgage indebtedness. Canada likewise met conditions similar to those in the U S.

Until 1925, agricultural production continued to expand with the perfecting of the gasoline tractor and large-scale machinery. Approximately 50,000,000 ac. of grass land were put into cultivation west of the Mississippi river in the United States, and extensive areas were added in Canada. Attempts to sell the increased production upon depressed world markets met both low prices and trade restrictions in European markets. In general, agricultural prices followed a downward trend until 1933.

The rapid development of improved highways and motor transportation started a revolution in marketing farm products following 1920. Trucking livestock to market stimulated the growth of smaller widely-scattered packing plants. Likewise. the truck made possible the expansion of whole-milk producing areas about cities and contributed to the establishment of larger creameries at central points.

Early legislative attempts to bring relief for low agricultural prices included the Federal Cooperative (Capper-Volstead) Act of 1922, the Federal Intermediate Credit Act of 1923, the Federal Agricultural Marketing Act of 1929, and the Smoot-Hawley Tariff Act of 1929.

The combination of low agricultural prices and revolutionary changes in marketing processes stimulated research in agricultural economics. In 1922 the federal work in farm management, markets, and crop and livestock estimates was further consolidated as the bureau of agricultural economics.

Research in this bureau followed lines which had been outlined in the reorganization plan of the office of farm management in 1919, and with increased emphasis on crop and livestock statistics and marketing. The research studies in marketing may be grouped under the four heads of (1) co-operative marketing; (2) commodity market operations; (3) special marketing facilities; and (4) research pertaining to regulatory problems. The first group of studies described and analyzed the development and problems of many types of co-operatives. The second dealt with inspection, grading and market services. The third included the reorganization of terminal produce markets, interstate trade barriers and the disposal of surplus farm produce. The fourth group of studies was conducted by various agencies, including the Federal Trade commission, the Tariff commission, the department of commerce, and some other divisions of the department of agriculture. Prominent among such studies were those of the grain trade and cotton trade.

Regulatory [illegible] the marketing of farm products experienced a [illegible] in this period in the administration of the Grain Futures act, the Cotton Futures act, the Packer and Stockyards act, and various warehouse developments —all of which were indicative of the forward steps being taken in the marketing and credit field.

During the same period, extensive discussion was given to measures designed to raise the level of farm prices. Prominent among the proposals were the equalization fee, the export debenture and the domestic allotment plans. Throughout this period the concept of parity prices for farm products was gaining in emphasis, although it did not find its way into legislative action until 1933. The results of research came prominently into the consideration of these legislative efforts. The expanding interest in and knowledge of the economic aspects of agriculture were reflected in the colleges and universities, especially the land-grant institutions in the direction given to research work, the heavy registration of students in agricultural economic courses and the broad program in agricultural economic extension.

The study of farm prices in relation to other commodities and the introduction of statistical and historical techniques of study were widely applied to agricultural economic problems in the period immediately following the close of World War I. In addition to the work initiated by Taylor in the Federal Bureau of Agricultural Economics should be mentioned that of G. F. Warren at Cornell university, although this work was rapidly expanded in many institutions.

The Purnell Act of 1925 made funds available for research in agricultural economics, home economics and rural sociology in the state agricultural experiment stations. These funds reached a level of $60,000 a year to each state in 1929, and gave rise to numerous research projects in the various phases of agricultural economics. Many state experiment station bulletins dealt with marketing and other economic problems of local importance, and furnished valuable material for teaching and extension. In addition, books, journal articles and federal publications have appeared pertaining to agricultural economics. The extent of the literature, from 1900, was exceedingly great.

Extension work in agricultural economics was sponsored jointly by the federal government and the state agricultural colleges following 1919. With the reorganization of the office of farm management, Taylor stimulated farm financial and production records for farmer use. The development of the account books adjusted to conditions in the respective states rapidly spread throughout the country. The University of Illinois was responsible for the development of the co-operative farm management associations sponsored by the University, but financed primarily by co-operating farmers. Similar co-operating groups have been formed in a number of states, particularly Minnesota, Iowa and Kansas. Economic outlook information for farmers, first sponsored in 1922 by the bureau of agricultural economics, is now an important extension project in practically every state. Likewise, marketing specialists within the states have given much time to

assisting co-operating farmers and organizations in the marketing of particular products

In addition to the agricultural experiment stations and state colleges of agriculture, much valuable work was done at Chicago, Harvard, Leland Stanford, Northwestern, Pennsylvania and other universities. Endowed research institutions, established following 1920, added impetus to agricultural economic studies. The Brookings institution at Washington, D C., while interested in broad economic studies, directed considerable study to agricultural problems The Food Research institute located at Stanford university, the Giannini foundation at the University of California, and the Farm foundation located in Chicago were primarily concerned with agricultural economic problems.

The deteriorating national economic situation following 1929 added to the misfortunes of agriculture, which continued to maintain a high level of production. There was unemployment and low purchasing power for farm products. It was this situation that led to the change of administration in 1933, to the agricultural phases of the New Deal. The tariff revisions in 1929 had brought little relief to agriculture. The disparity in the prices of the farm products and the goods and services purchased by farmers, together with the heavy mortgage indebtedness, resulted in the ruin of many farmers

It was the impact of these conditions that brought a number of important federal laws into effect. Among the more important of these are: the Agricultural Adjustment Act of 1933 with subsequent amendments; the Farm Credit Act of 1933; the Soil Conservation Act of 1935; the Agricultural Marketing Agreement Act of 1937; the Farm Tenant Act of 1937; and the new Agricultural Adjustment Act of 1938.

This legislative emphasis upon the economic problems of agriculture was paralleled by many studies pertaining to credit, market disposal, land tenure, land use, conservation of soil and the control of production. The controls over agriculture designed to rid the country of burdensome surpluses and to bring production into adjustment with demand continued until the outbreak of World War II.

The coming of the war found agriculture with abundant supplies of crops and livestock on hand, which enabled the farmers of the United States to greatly expand their production to meet the wartime demand. The war period brought an unlimited demand for agricultural products, leading to more attention to adjustments in the production and distribution of agricultural products to better meet national needs. After the outbreak of the war, emphasis was placed upon the production of maximum amounts of needed food per acre, per animal and per unit of labour or power. This period has led to many wartime organizations, including the Office of Price Administration, the War Food administration, Foreign Economic administration, Combined Food board and the United Nations Relief and Rehabilitation administration. These organizations, many of whose functions are economic in character, will not be treated here until their place, functions and accomplishments can be better appraised.

The period 1900–1919 marked a notable expansion in agricultural economics teaching, research, extension and regulatory work; the developments after that date were toward greater integration and toward work of a more vital character Within the agricultural colleges, teaching, research and extension in agricultural economics have become progressively more closely knit. Instructional and research subjects included farm management, co-operation, marketing, agricultural prices and statistics, finance, agricultural economic history, agricultural economic geography, land economics, rural sociology and agricultural policies. Agricultural labour, agricultural law, the appraisal of farm real estate and buildings, and rural government have received attention. Agricultural economics thus has drawn upon the various social sciences to make its contributions more practical.

**Great Britain.**—Following 1900 to the close of World War I in 1918, the general economists in the British Isles helped to refine the analysis of economic problems pertaining to agriculture. During this period little was developed of a statistical nature in the study of agricultural problems, but economic reasoning was applied to questions pertaining to policy, especially in the field of land tenure, marketing, land management and international trade.

In Great Britain, agricultural economics has had a somewhat different emphasis than in the United States. In agricultural economics research writings and teaching greater emphasis was put upon agricultural policies, although the problems of the individual farmer were continually stressed from a practical point of view.

The subject of agricultural economics was taken up by the ministry of agriculture and fisheries, but resources were limited prior to World War I. Assistance, however, was made available from the Development fund and from the University of Oxford An Institute of Agricultural Economics was established at Oxford. Its activities were, at first, directed to the improvement of farm accounts, especially by the use of the cost accounts. As further resources became available, its scope was broadened and important investigations were undertaken in other phases of the field. In addition to Oxford, Cambridge university and the University College of Wales took initiative in conducting agricultural economic studies. Also, agricultural economics was placed in most of the agricultural colleges of the British Isles by 1930, and the provincial agricultural agents were serving as economic advisers in their respective areas.

Following 1920 research was expanded to include marketing, especially with the formation of the Empire Marketing board. To quite an extent the agricultural economic problems in Great Britain, like those of the United States, were accentuated by World War II. As a deficit food country, the United Kingdom was in a better position to regulate trade in agricultural products than many other countries. Canada, Australia and Argentina, as well as the United States, continued to supply cheap wheat to Europe. The cheap feed supply encouraged the expanded production of dairy products in Denmark, Holland, Switzerland, Finland and New Zealand, and, in turn, contributed to low world prices for these products. Barriers to free trade in Europe tended to force uneconomic agricultural production adjustments within countries. The problems were accentuated by maladjustment in trade and delayed agreements concerning war reparation settlements.

In the United Kingdom various schemes for promoting production of agricultural products were undertaken. These included subsidizing the production of sugar, wheat and hogs, and the development of marketing schemes designed especially to stabilize the production of dairy products and hogs. The United Kingdom, dependent upon the importation of much of its food supply, sought to stabilize its domestic agriculture on a basis which would encourage production by providing definite quotas of agricultural imports. The Ottawa agreements, for example, provided for preferential trade in wheat and some other products.

The growth of interest in agricultural economic matters in the British Isles is reflected in the formation of the English Agricultural Economics society and in its published proceedings, as well as in the publications of the ministry of agriculture and fisheries, the Empire Marketing board, and in university publications.

**Selected Continental European Countries.**—Agricultural economics has attained more prominence in western European countries where the peasant populations supply farm products to industrial markets. To the east of these countries, that is, in the area between the Baltic, the Adriatic and the Black seas, there have been more pressing farming problems. After 1900 the increase in wheat production outside of Europe and, during the inter-war period, the fall in prices of farm products, the prolonged depression and, finally, the closing of markets for imported food products in western Europe, brought hardships to many countries, especially to those in eastern and southeastern Europe. These and other agricultural problems stimulated work in agricultural economics, especially in the more industrialized European countries.

Several of the larger countries on the continent of Europe have aimed at being self-sufficing in food. The service of agricultural economics in these countries has been directed to these social ends as well as to the development of better organization of farms.

**France.**—The land survey (cadastre), dating its modern phase from about 1790, has had continued development. Appraisal technique for farm properties, nurtured by a professional organization founded in 1838, has likewise had continued development. E. Jouzier gave impetus to economic studies through his *Economie Rurale* (1903). Agricultural policies have been the object of considerable research by French economists. French peasants, generally, have been indisposed to make available facts as to the results of their farm and investment activities. The virtual absence of farm accounting work has retarded economic research in France.

**Germany.**—Agricultural prosperity has been a goal of German statesmen since about 1870. The Bismarckian philosophy extended practically to the establishment of the Weimar constitution, 1919. A third main phase of German economic policy making began in 1933. In tariff and other protectionist policies, and other phases of study, agricultural economists were active prior to the Weimar constitution, reached a high development under it, and suffered considerable eclipse after 1933.

Influential in economic thought on German farm problems at the turn of the 20th century were T. von der Goltz, [illegible], M. Sering and others. Contributions to farm accounting, management and appraisal were numerous. Agricultural geography, history and policy were subjects of many treatises. The welfare of agricultural labourers as well as of tenants and landlords was examined statistically. Prior to 1933 there were many points of similarity in the breadth, depth and volume of scientific work in agricultural economics in Germany and in the United States.

Economic developments continued in German agriculture from 1933, but with considerable change in the personnel in governmental and university posts. The emphasis on self-sufficiency in foodstuffs increased under the nazi regime. The Food Estate (*Naehrstand*) was given control of farm and food problems. Upward trends in yields were a prime object in government policy. The land valuation services of the treasury were reactivated to provide a basis for adjusted tax rates promised the farmers for their support of the nazi program. Peasant holdings were made the object of hereditary farm legislation, affording some of the effects of the principle of entailing which had long been enjoyed by the estate farms in eastern Germany. Both under the Weimar constitution and subsequently, the political and economic influence of these large landholders continued with little disturbance. Rising land prices and other symptoms of effective protection to producers of farm products and holders of property continued into the World War II period.

Marketing as well as production and its land tenure basis came in for readjustment under the nazi regime. For example, boundaries were specified beyond which whole milk for table use might not be drawn into a city. Taxes applied to producers within the favoured area were used in part to reimburse those outside who must find other, usually less profitable, outlets. Perhaps, with the exception of Russia, the agricultural economy of Germany has undergone control more than that of any major country.

Recent contributions of German agricultural economists have been directed toward carrying out the administrative policies set by the national pattern. In general, new names appear as authors. These publications, however, show fewer comparisons of economic experiences within the country with those outside.

**Italy.**—By 1900, Italy had a background of scientific work on the land survey (cadastre) and in farm real estate appraisal methods extending back many decades. Creditable publications on land valuation were produced early in the 19th century, and other developed lines of agricultural economic work appeared toward its close. Prominent among economic theorists who made applications to agriculture was S. Iacini, about 1870. Also to be noted are G. Valenti, in agricultural statistics, and V. Niccoli (Milan and Pisa) and O. Bordiga (Portici), both of them university professors, who emphasized farm management, from 1900 to 1915.

Italian rural economy was in a disorganized condition at the end of World War I. It was then that A. Serpieri and other agricultural economists promoted the organization of the National Institute of Agricultural Economics and Statistics. In 1927, the work in statistics was taken over by the Central Institute of Statistics. Research centres of agricultural economics were established at Bologna, Florence, Perugia and Portici.

Agricultural economists in Italy have brought the points of view of history and sociology into their studies. They have given much attention to agricultural labourers, to land reclamation and to mountain populations.

**International Aspects of Agricultural Economics.**—International conferences have dealt with many economic problems in agriculture from 1864. A single product, sugar, received major attention for about 25 years. From about 1890 to 1942 international meetings, largely prompted by import and export problems, included more and more countries and more farm products Notable were the Chadbourne Sugar Plan of 1931 and the International Sugar Agreement of 1937. Rubber, in 1922, was subjected to the first operation of the Stevenson plan. In 1934 the International Rubber Regulation scheme was effected. No less than 16 international conferences were held in 1930 and 1931, primarily with regard to wheat. Under an agreement in 1933, a Wheat Advisory committee was formed which led, in June 1942, to the establishment of the International Wheat council, with provisions for semiannual sessions. In addition to efforts to bring about international regulation of production, exports and, to some extent, prices, international meetings have established world standards and grades, especially for cotton and wheat.

Apart from these farm commodity conferences, several types of agencies have promoted agricultural economic discussions at the international level. The International Commission of Agriculture called international congresses of agriculture. Beginning with the first session at Paris in 1889, 18 major sessions were held in 40 years. Relations between landlord and tenant claimed major attention at the Paris session. The second session, held at the Hague, 1891, is typical of the earlier meetings; it included seven sections, three of which were devoted to rural economy, credit institutions and legislative questions. In addition, some attention was turned to discussion of land nationalization, transportation of farm products and tariffs affecting agriculture. At Dresden, in 1939, there were nine sections which included (1) agrarian policy and farm management, (2) agricultural co-operative societies, (3) agricultural industries and (4) rural life and the work of the countrywoman. Both private and social economic emphasis has persisted in these farm congresses.

At the Budapest congress in 1896, David Lubin projected the idea of an international chamber of agriculture. The International Institute of Agriculture, founded at Rome, in 1905, realized a part of the goals included in the original project. Emphasis on agricultural economics gained impetus in 1933–35, when H. C. Taylor was the representative of the U.S. on the permanent committee of the institute. The institute has made outstanding contribution in its statistics and records of legislative enactments. The institute's efforts for a world agricultural census in the late 1920s, and again in the late 1930s, have had more than pioneering value. Numerous publications dealing with principal farm products on the world market and with broader problems of agriculture, as treated in *Agricultural Problems in Their International Aspect* (in co-operation with the League of Nations) (1923), and *World Trade in Agricultural Products* (1940), are of lasting economic value. The same applies to numerous articles in the *International Review of Agriculture*, one of the organs of the institute. In its library and other collections of data, the institute is unique.

The International Commission of Agriculture maintained several units. One of these was the International Confederation of Agriculture, and developed, about 1920, plans for separate biennial meetings in years in which the congresses were not convened. The confederation meetings for the most part have dealt with economic problems with which national farm organization leaders, primarily in Europe, have been confronted. The May 1938 report listed 14 international meetings in which economic aspects of agriculture were involved.

The International Federation of Surveyors has placed emphasis on valuation of farm real estate since about 1920.

The International Conference of Agricultural Economists was instituted in 1929 at Dartington hall, Devonshire, England. Subsequent sessions were held at Ithaca, New York, in 1930, Bad Eilsen, Germany, in 1934, Saint Andrews, Scotland, in 1936, and Macdonald college, Canada, in 1938. Published proceedings of these conferences show participation well divided between European and North American agricultural economists. Special publications on agricultural conditions in different countries of Europe appeared following the Bad Eilsen conference, and an *International Journal of Agrarian Affairs* was launched in 1939.

The United Nations Conference on Food and Agriculture, Hot Springs, Virginia, 1943, was followed by an Interim Commission on Food and Agriculture and provided for a permanent United Nations Food and Agricultural organization. The appraisal of the work of these agencies as of other agencies of the period of war and its aftermath is not to be made now (1944).

BIBLIOGRAPHIC NOTE:—In the United States, in particular, some of the more important current contributions are not included in books and are to be found through the use of bibliographic lists.

The United States department of agriculture has published in its *Bibliography of Agriculture* (monthly) current reference lists on agricultural economic subjects since July 1942. Similar current bibliographies were included, 1927–1942, in *Agricultural Economic Literature;* periodical articles and bulletins on economic aspects of agriculture have occupied a growing place in periodical indexes as *Agricultural Index,* 1915–date, *Bulletin of the Public Affairs Information Service,* 1914–date, and the *International Index to Periodicals,* 1913–date.

In its new series, also, the *United States Department of Agriculture Library Lists* and *Bibliographical Bulletins* include economic references.

Lists prepared in the division of bibliography, Library of Congress, 1900–1946, contain economic references especially for the period prior to the development of bibliographic services in the department of agriculture.

Agricultural economic bibliographies have been issued by various state and other institutions of research. To be noted is the *Wheat Studies,* Food Research institute, Stanford university.

The International Institute of Agriculture, Rome, published in English after 1938 an *International Bibliography of* [illegible] *Economics* (quarterly). This appeared, 1934–38, in *Berichte ueber Landwirtschaft* and was issued separately.

Lists of agricultural economic bulletins, periodicals and other publications of the national state and provincial departments of agriculture, the experiment stations and colleges and other institutions of research are available from the respective sources.

Among the many books that might be cited the following have been prominent and are representative:

United States: P. W. [illegible] and J. I. Falconer, *History of Agriculture in the Northern United States, 1620–1860* (1925); J. D. Black, *Agricultural Reform in the United States* (1929); T. N. Carver, *Principles of Rural Economics* (1911); A. A. Dowell and O. B. Jesness, *The American Farmer and the Export Market* (1934); R. T. Ely and G. S. Wehrwein, *Land Economics* (1940); G. W. Forster, *Farm Organization and Management* (1938); L. C. Gray, *History of Agriculture in Southern United States to 1860* (1933); B. H. Hibbard, *The History of Public Land Policies* (1924); E. G. Nourse, *Agricultural Economics* (1916) and *American Agriculture and the European Market* (1924); T. W. Schultz, *Redirecting Farm Policy* (1943); W. J. Spillman, *Farm Management* (1923); H. C. Taylor, *Outlines of Agricultural Economics* (1925, 1st ed., 1905); G. F. Warren, *Farm Management* (1913).

British Isles: A. W. Ashby, *Allotments and Small Holdings in Oxfordshire* (1919); R. E. Ernle, *Prothero, English Farming, Past and Present* (5th ed., 1936); C. S. Orwin, *The Determination of Farming Costs* (2nd ed., 1921); R. H. Rew, *A Primer of Agricultural Economics* (1927); J. A. Venn, *The Foundations of Agricultural Economics* (1938, 1st ed., 1923).

Selected Continental Countries: Friedrich Aereboe, *Allgemeine Landwirtschaftliche Betriebslehre* (6th ed., 1923); F. Aereboe, J. Hansen und T. Roemer, *Handbuch der Landwirtschaft* (5 vol., 12th to 15th ed., 1928–1930); T. A. L. G. von der Goltz, *Geschichte der deutschen Landwirtschaft* (2 vols., 1902–1903) and *Leitfaden der Landwirtschaftliche Betriebslehre* (vol. II, 7th ed., 1922); Etienne Jouzier, *Economie Rurale* (1903); Ernst Laur, *Einfuehrung in die Wirtschaftslehre des Landbaues* (2nd ed., 1930) and *Grundlagen und Methoden der Bewertung, Buchhaltung, und Kalkulation in der Landwirtschaft* (3rd ed., 1928); Kurt Ritter, *Der Getreideverkehr der Welt vor und nach dem Kriege* (1926); Walther Rothkegel, *Handbuch der Schaetzengslehre fuer Grundbesitzungen* (vol. 1, 1930; vol 2, 1932); Max Sering, *Die deutsche Landwirtschaft unter Volks-und Weltwirtschaftliche Gesichtspunkten* (*Berichte ueber Landwirtschaft,* new series, Sonderheft 50, 1932); Albrecht Thaer, *Grundsaetze der rationellen Landwirtschaft* (new ed., 1880); J. H. von Thunen, *Der Isolierte Staat* (3rd ed., 1930).

Nongovernmental periodicals giving prominence to agricultural economic materials include the following: *Jour. of Farm Economics; Jour. of Land and Public* [illegible] *Jour. of the American Society of Farm Managers and Rural Appraisers; Economic Geography; Proceedings of the British Agricultural Economics Society; Kuehn-Archiv* (since 1911), *Deutsche Landwirtschaftliche Presse* (since 1874), *Journal fuer Landwirtschaft* (since 1853), and *Landwirtschaftliche Jahrbuecher* (since 1872).

(C. L. ST.; H. C. M. C.)

**AGRICULTURAL EDUCATION.** Though agriculture is the oldest and greatest of industries, agricultural education in any organized form is among the recent activities of modern states. In Great Britain, or at least in England and Wales, it may be said to go back only to 1890. It would be untrue, however, to say that before then nothing was done. Chairs of agriculture and rural economy were founded at Edinburgh in 1790 and at Oxford in 1796; the Royal Agricultural college at Cirencester was established in 1840. But agricultural education provided in universities or colleges was beyond the reach of the bulk of the agricultural population. Little or nothing was offered to the children of farmers, smallholders and labourers until nearly the end of the 19th century. In 1890, the Local Taxation (Customs and Excise) act placed at the disposal of county councils a sum of money (popularly known as the "Whiskey Money," because it was derived from an increase of the taxation on spirits which was originally destined for another purpose), amounting roughly to £750,000 a year, and authorized them to apply it to purposes of technical instruction, including instruction in agriculture. From 1890 onward there was a considerable, if slow, increase both of the higher education provided by university departments of agriculture and agricultural colleges, and of instruction provided by county councils. By 1912 the state was granting £19,000 a year for higher education, and the English and Welsh county councils were spending £70,000 a year on the more elementary instruction. World War I stopped the development of plans already prepared for further expansion on a relatively large scale.

**Postwar Development.**—The present system, though it follows prewar lines in its organization, is largely the creation of the years since 1918. It falls into two main parts; the university departments of agriculture and agricultural colleges, whose distinctive mark is that they provide a long course, two years at least, usually three, leading to a diploma or degree; and the education provided by county councils, which is essentially an education of short courses intended for the boy or girl who is already working on the land and proposes to return to it.

Higher agricultural education in England and Wales (excluding veterinary education) is provided at 14 centres, of which seven are departments or schools of universities, and the other seven are agricultural colleges, each possessing its own governing body, and not forming an integral part of a university. Eleven of these institutions (all except the Royal Agricultural college at Cirencester and the two women's colleges at Swanley, in Kent, and Studley, in Warwickshire), discharge an important function outside the actual teaching of students. Each is an "Advisory centre" for a group of counties forming its "Province"; it is provided with specialists in the more important branches of science bearing on agriculture, such as chemistry and entomology, who supplement the more general advice provided for farmers by the technical staffs of county councils, and it acts as a unifying and co-ordinating influence for the experimental and advisory work of county councils. All the 14 institutions are recognized and aided by the state. The cost to the student varies considerably between the two Welsh colleges (Aberystwyth and Bangor) at one end of the scale and Oxford or Cambridge at the other end.

Education of a less elaborate character is provided by county councils; in some counties by means of a farm institute (a simpler and smaller agricultural college, usually possessing residential accommodation and a farm attached), in practically all counties through organized classes, held at no special institution, or through discussion clubs, evening lectures and similar less systematic methods. In 1927 there were 16 farm institutes, four in Wales (including Monmouthshire) and the remainder in England, all but one supported and governed by county councils. On the average they can accommodate 40 students each; the fees for board,

lodging and tuition vary between 17s. 6d. a week for students coming from the county which supports a particular institute to £2, 10s. od a week for other students. The main course at a farm institute is normally a six months' winter course in practical agriculture, extending from October to March, and designed for young people, from the age of 16 upward, who have been working on the land and are going straight back to it. During the summer months the institute is used for courses in dairying, poultry keeping and other special subjects The great majority of county councils, however, do not possess farm institutes, but attempt to take agricultural education to the landworker by such means as the organized day course (a continuous course of instruction held at regular times, usually one day a week, in any town or village where there is a demand for it, and extending over several weeks or perhaps months), evening classes, travelling dairy schools, courses for instruction in manual processes (plowing, hedging, ditching, milking, and the like), and lectures or demonstrations.

In 1937–38 the cost of the education provided by county councils in England and Wales was £420,000, of which the government provided a fraction over two-thirds and county rates the remainder. One other activity deserves mention. In 1922 the government started a scheme of scholarships in agriculture for the sons and daughters of agricultural workmen and of other rural workers in a similar economic position. Under this scheme approximately 100 scholarships are awarded every year, of which the great majority are short-term scholarships to farm institutes. The cost is £20,000 a year.

In Scotland, agricultural education has followed a rather different course, though it started on the same lines. The organization is not divided between universities and colleges on the one side and county councils on the other; the colleges control and direct the whole system. Apart from the small sums received as fees, the whole cost is met by grants from the state, which in 1925–26 amounted to £75,000. But in the education given, as distinct from the organization for giving it, the Scottish system resembles the English The three colleges in alliance with their respective universities provide long courses (three winter sessions) for the university degree or college diploma; they take the place of the English farm institutes by including in their curricula short courses for farming; and through the appointment of organizers resident in the counties they conduct extension work similar to that done in England and Wales by the staffs of county councils. Two special institutions should be mentioned: the Kilmarnock dairy school and the Craibstone School of Domestic Economy for Women, the former associated with the Glasgow college and the latter with Aberdeen.

**Other Systems.**—Broadly speaking, and with considerable variations due to differences of national character and environment, continental systems tend to fall into the main divisions already enumerated, of two or three years at universities or agricultural colleges; in the second place, there are short courses of a few weeks or months in the dead season, or of a year at most, at a residential institution—sometimes a college, more usually a farm institute or farm school: thirdly, miscellaneous courses, lectures, and demonstrations given by peripatetic instructors who endeavour to bring technical education to the farmer's door, or at least to his town or village. But there are one or two features of foreign systems which ought to be mentioned, if only by way of contrast to the British system.

Of these the most striking is, perhaps, the large part taken in Germany, Denmark, Sweden, and in fact nearly all over the continent of Europe, by voluntary societies and associations: in Denmark, for instance, agricultural societies own and manage many of the Folk high schools and support many agricultural counsellors—experts who combine teaching, lecturing and advisory functions. But the Folk high schools of Denmark are notable not merely as an example of voluntary effort, they are a great and successful attempt to add a finish to the education of the adult land-worker by giving him or her a six to nine months' course, not entirely agricultural and sometimes not agricultural at all, at a residential institution. In Belgium, a country of smallholders, there is a highly developed system of instruction for women and girls in a combination of practical agriculture and rural domestic economy; the system centres in the national institution at Laeken In Sweden also (besides the usual agricultural colleges, agricultural schools, and farmers' sons' schools, the last providing a three months' theoretical course for young men usually about the age of 22) there are something like 40 schools of agricultural economy for women.

**Changes in the British System.**—From 1924 or thereabouts two movements affecting agricultural education have gained prominence. The first is the movement for imparting into the ordinary subjects of instruction taught at rural elementary and secondary schools what is known as a rural bias—*e.g.*, arithmetic may be taught through simple farm accounts, or geography with at least some reference to the physical characteristics of the district in which the school is situated Provided it does not degenerate into a premature attempt at vocational training, there is everything to be said in favour of such a change.

The second change is a change of emphasis in the subjects usually taught in agricultural institutions and courses. Hitherto syllabuses of instruction have tended to be dominated by science, or rather sciences—chemistry, physics, botany A school of thought has arisen which starts from the fact that the farmer is not only a grower of crops, a producer of eggs or milk, a breeder of stock, but also a manager of labour, a buyer of goods, and a seller of products—in the ordinary phrase, a businessman. There is consequently a steady pressure toward modifying courses of instruction, particularly the short winter courses, by giving a larger place to such subjects as accounts (the foundation of business), the management of labour, and the elements of marketing technique. There can be little doubt that this side of agricultural education has been relatively neglected; but the teaching of management is not easy

**Defects in the British System.**—But though these changes may be beneficial, the British system still reveals several notable defects. First, it is far too small, not, perhaps, for the demands which are actually made on it, but for the demands which ought to be made. In the second place, the larger part of the English and Welsh system—the part organized and directed by county councils—is "patchy." There is no power to compel county councils to supply even the barest modicum of agricultural instruction, and accordingly the provision made for it in a county varies with the character and finances of the county council and its electorate. Thirdly, provision for the residential education of adults—one of the most marked and successful features of continental systems—is noticeably absent. Lastly, provision for instruction in manual processes and in the handling of machinery, though not absent, is not so common as it should be.

**Progress Being Made.**—Some of these defects are being slowly remedied. In spite of financial exigencies, college and county education does progress and grow; and, best of all signs, authorities are agreed that since 1900 there has been a remarkable change of attitude on the part of the agricultural community.

Farmers welcome the assistance of college and county staffs; and a first attempt has been made, through private enterprise, to provide at Avoncroft, near Evesham, an institution very similar to the Folk high school of Denmark for adult land-workers. If that experiment proves a success, it may be the beginning of a new era. Moreover, the education of women and girls has recently been investigated by a strong committee, which has surveyed the whole field; and the ministry of agriculture has put before county councils a detailed scheme for extending instruction in manual processes. In 1925–26 the number attending such instruction rose to 1,900—a number which, however small in itself, was at least an increase of 50% from the previous year.

### IN THE UNITED STATES

Agricultural education in the United States finds its beginnings in the striving of individual landowners toward higher levels of production. This created interest and discussion in agricultural communities, induced the making of tests, trials and observations, pointed to the advantages of concerted action, and slowly but steadily laid the foundation on which present-day educational machinery was built

**Agricultural Schools.**—Among the early attempts to provide agricultural instruction in schools of less than college grade the following may be noted: In 1821 the state legislature of Maine granted to Robert Hallowell Gardiner an annual appropriation of $1,000 for the maintenance of an institute for agricultural and mechanic arts. The Gardiner Lyceum was opened at Gardiner, Me., in 1823. It employed a professor of agriculture, maintained a farm and offered short winter courses in agriculture. An agricultural school was founded at Derby, Conn., in 1826. So-called manual labour schools were established in New York state in the period 1825–40. They laid stress, in their curricula, on vocational training in agriculture and the industries. In 1845–50 several agricultural schools were founded, through private initiative, in New York and Connecticut. After the middle of the 19th century conditions became more propitious for the teaching of agriculture in elementary and secondary schools. A period of agitation was followed by the establishment of an agricultural high school at the University of Minnesota (1888). District and county agricultural schools were created a few years later, among them the agricultural schools in the nine congressional districts of Alabama.

By 1898 there had been established ten agricultural high schools. In 1909, there were 60 separate agricultural high schools. Agricultural courses were then being offered in 346 other high schools. Several states, among them Massachusetts (1911), New York (1913), Pennsylvania (1913), New Jersey (1913) and Indiana (1913) had established definite systems of vocational agricultural education.

It is estimated that in 1912–13 there were about 2,300 state agricultural schools, district agricultural schools, agricultural departments of high schools and ordinary schools that maintained systematic instruction in agriculture.

The Smith-Hughes Vocational Education act (1917) provides federal aid for vocational training, including the teaching of agriculture and home economics in secondary schools. Since the passage of this act many vocational agricultural schools, as well as agricultural departments of general high schools, have been established in the several states. Of the 11,561 rural high schools, 3,339 or 29% maintained vocational agricultural departments in 1927. They had an enrolment of 129,032 students. In that year there was available for the support of vocational agricultural education nearly $7,500,000, compared with about $740,000 in 1918.

The George-Deen act (1936) greatly increased federal funds and by 1942 a total of about $15,000,000 was being expended for 610,000 agricultural students. It may be noted, further, that many states have special laws which concern the teaching of agriculture in elementary rural schools.

**Agricultural Colleges.**—Simeon de Witt, surveyor-general of New York, published, in 1819, a pamphlet entitled *Considerations on the Necessity of Establishing an Agricultural College, and Having More of the Children of Wealthy Citizens Educated for the Profession of Farming.* A state agricultural college was established in New York in 1853. The oldest surviving state agricultural college is that of Michigan (1857). Similar colleges were established in Pennsylvania and Maryland (1859) and the incorporation of agricultural colleges authorized in Iowa and Minnesota (1858). The Federal Land Grant act (also called the first Morrill act) was passed in 1862. It created a group of state institutions of higher learning, known as the land-grant colleges and universities (*q.v.*). This legislation was far-reaching in its effects on the social and economic development of the country. The second Morrill act (1890), the Nelson amendment of the Morrill act (1907) and the Bankhead-Jones act (1935) provided additional funds for the state colleges. In 1936–37 the 69 land-grant colleges enrolled 21,254 agricultural students.

The state colleges and universities are intimately associated with the U.S department of agriculture This had its inception in the collection and distribution of seeds and plants by the patent office in 1839. The service was expanded to furnish information on various agricultural topics In 1862 the department of agriculture was organized as such and in 1889 its head became a member of the president's cabinet. When the Hatch act was passed (1887), funds were made available for the establishment of experiment stations as departments of the state colleges. Prior to that, state agricultural experiment stations had been established in Connecticut (1875), California (1877), North Carolina (1877), New York (1879 and 1882), New Jersey (1880), Ohio, Tennessee and Massachusetts (1882), Alabama and Wisconsin (1883), Nebraska (1884), and Michigan, Indiana, Kentucky, Maine and Minnesota (1885) A private sugar planter's experiment station was established in Louisiana in 1885, and state stations in Louisiana, Vermont and New Hampshire in 1886

In keeping with the provisions of the Hatch act, an office of experiment stations was organized in the department of agriculture for the purpose of maintaining contracts with the stations Subsequent legislation referred to as the Adams (1906), the Purnell (1925) and the Bankhead-Jones (1935) acts augmented the income of the stations, established better correlation of research on a regional and national basis and encouraged cooperation among the stations themselves and with the department of agriculture. The stations are primarily research institutions. As such they are maintaining many hundreds of research projects of direct significance to agriculture and the farm home, and creating a vast body of knowledge from which facts and generalizations are being drawn for the benefit of resident instruction and of extension teaching.

The Smith-Lever act was passed in 1914. It represents a national scheme of extension teaching in agriculture and home economics and is the culmination of a long series of local, state, regional and national efforts to stimulate agricultural progress by bringing technical and general information to the farm and farm home.

The antecedents of the Smith-Lever act include the almanacs, agricultural journals and newspapers, agricultural societies, boards of agriculture, farmers' institutes and demonstrations and lectures by public-spirited individuals. The act provides for county agents, home demonstration agents, club leaders and extension specialists. It makes the department of agriculture responsible for coordinating and supervising the extension activities in the several states. The work was further developed by the Capper-Ketcham act (1928) and the Bankhead-Jones act (1935).

The agricultural teaching, research and extension of the land-grant colleges and universities are being generously supported by the local, state and federal governments. In 1936–37 the federal government appropriated $17,256,207 for the support of agricultural extension, while the states, counties, farm organizations and individuals were expending for the same purpose $12,507,455.

Ross, *Democracy's College, The Land-Grant Movement in the Formative Stage* (1942). (J. G. L.; X.)

**AGRICULTURAL ENGINEERING,** broadly speaking, is the science of utilizing in combination the forces and materials of nature for the benefit of agriculture; specifically it implies an understanding of biology, soils science and agronomy, as a basis for the intelligent application of engineering principles to agriculture.

While agricultural engineering deals entirely with agriculture, it is related more or less to several other important branches of engineering, as, for instance, mechanical engineering, which has to do with the design and construction of steam and gasoline power units, railroad and factory equipment, and mechanical de-

vices generally. But agricultural engineering makes use of the principles here involved in the design of mechanical farm power units and machinery to perform the many and complex farm operations. It is related to electrical engineering, which has to do with the design and construction of electric power installations, transmissions and distribution lines, in that agricultural engineering puts the electricity to work on the farm in energizing electric motors to grind feed, milk cows, in providing current for electric fences and other equipment, and in performing some 200 other chores. It is related to civil engineering, which, among many broad problems, handles those incident to the extensive storage and arterial distribution of irrigation water and to the design and construction of large community drainage systems. On the other hand, agricultural engineering sees that the irrigation water is economically distributed and applied to crops and that in drainage the ditches and underdrains are scientifically planned to suit each field and the use to be made of the land. The civil engineer is also charged with the design and construction of large steel and concrete buildings whereas the agricultural engineer applies the principles of construction to the design of farmhouses, dairy barns and other animal shelters, storage facilities for farm crops, and miscellaneous farm structures and equipment.

It is generally recognized that the marked advance in agriculture since 1850, especially the great increase in convenience in doing work and the large reduction in labour per unit of production, has been due in no small measure to improved engineering practices and more and better machines. Thus the development of farm land from the wilderness by clearing, the control of erosion by terraces, the disposal of surplus water and the acquiring and regulating of the water needed for plant growth and for human and animal consumption are problems of the agricultural engineer. The erection of farm structures of all types, with their problems of light, heat, ventilation, etc., and the best use and design for the machinery and implements used in farm operations and transportation, as well as the sources of the power which operates them, also are in the field of the agricultural engineer In the United States this has been a natural consequence of a rapid increase in engineering of all kinds that came with the sudden opening up of great natural resources. In Great Britain and continental Europe, however, the scope of agricultural engineering is less specialized, the tendency being rather to give practical recognition to two distinct divisions of the science, dealing respectively with the mechanical phases (implements, machinery and power) and those of the soil (irrigation, drainage, erosion control, etc.).

Agricultural engineering as a profession got its start at Iowa State college, Ames, Iowa, where the first four-year course leading to a B.S. degree in agricultural engineering was established in 1905. Two years later the American Society of Agricultural Engineers was founded with a charter membership of 17. This number had increased to 1,300 by Jan. 1, 1944, mostly in the United States, but the membership includes citizens of Argentina, South Africa, Australia, Brazil, Canada, Colombia, Cuba, Ecuador, England, India, Mexico, Peru and Scotland. Before the outbreak of World War II there were members in Germany, Greece, Hungary, Netherlands, Norway, Panama, Sweden and Switzerland.

In the United States in 1941, 22 state agricultural colleges maintained courses leading to a degree in agricultural engineering, while several others, though they did not grant degrees, offered courses that constituted a virtual recognition of the science. In the United States, too, more than 100 agricultural engineers in various states were engaged in 1944 in full time extension activities—carrying to the farmer the results of agricultural engineering research in farm power and machinery, rural electrification, farm structures, soil conservation, and mechanical processing. Outside the United States, in 1941, the only degree course being offered in agricultural engineering was in Canada. In 1942 the only agricultural engineering education department in southern Asia was established at the Allahabad Agricultural institute in the heart of India.

The importance of agricultural engineering is further emphasized by the appearance in 1930, and each year thereafter, up to and including 1939, of the *International Directory of Agricultural Engineering Institutions* published by the International Institute of Agriculture at Rome, Italy. This lists the institutions of some 45 countries throughout the world which have studies under way dealing with agricultural engineering problems For each institution information is given regarding the exact address, scientific staff, research work in progress, equipment, publications which have been issued since 1932 and the languages which may be used in correspondence. (*See* also articles on AGRICULTURAL POWER AND MACHINERY; FARM BUILDINGS; RURAL ELECTRIFICATION; TILLAGE MACHINERY; HARVESTING MACHINERY; etc.)

BIBLIOGRAPHY – The bibliography of agricultural engineering consists chiefly of [illegible] dealing with its various component subjects. *See* [illegible] U.S. department of agriculture and those of the state agricultural experiment stations and extension services; publications of the American Society of Agricultural Engineers (St. Joseph, Mich); Institute of Agricultural Engineering (Oxford university); the Royal Agricultural Society of England (London); Konferenz Schweizerischer beamter Kulturingenieure (Lucerne), Die Technik in der Landwirtschaft (Berlin); Génie Rural (Paris). *See* also George Kuhne, *Handbuch der Landmaschinentechnik* (1928–34), J. Schaenzer, *Rural Electrification* (1940); Carter and Foster, *Farm Buildings* (1941); Archie A. Stone, *Farm Machinery* (1942). (R. B. G)

**AGRICULTURAL GANGS,** groups of women, girls and boys organized by an independent gangmaster, under whose supervision they execute agricultural piecework for farmers in certain parts of England. The evils of this system were so great as to lead to the passing of the Agricultural Gangs act (1867), forbidding the employment of any child under eight years of age, and of any female under a male gangmaster unless a female licensed to act as gangmistress were also present. Gangmasters must be licensed by two justices, and may not hold a liquor licence Later legislation made more stringent the regulations under which children are employed in agricultural gangs. By the Elementary Education act (1876), repealing and re-enacting the principal provisions of the Agricultural (Children) act of 1873, employment of all children under 11 was forbidden and restricted under 13. By the Education act of 1921, it is forbidden under 12 and restricted under 14. In 1940, in order to meet the exigencies of war, the provisions of this act were temporarily relaxed; local education authorities were, however, required to supervise the employment of school children, and to satisfy themselves in regard to hours of work, meals and other conditions.

**AGRICULTURAL INSURANCE.** Farmers have need for several kinds of insurance on property and on persons. Insurance contracts are made with farmers by (1) capital stock companies, (2) mutual companies or associations, (3) reciprocals or interinsurance exchanges, and (4) state or government funds or departments. Insurance on farm animals and growing crops is of types found only in agriculture. Risks involved have a different degree or character when in an agricultural setting; for example, farm buildings are usually isolated from the buildings of neighbours and are often remote from community fire-fighting facilities.

Insurance of farm buildings, crops in process of growth, livestock, motor-driven vehicles, and various items of personal property will be treated first in this article. Then will follow reference to employer's liability insurance, and health, life and various social security provisions.

**Fire and Lightning Insurance.**—Insurance equal to 75% of values of buildings and associated property items has been carried by many farmers against fire and lightning hazards. The amount of fire and lightning insurance in force on farms served by 1,885 mutual companies in the United States in 1941 exceeded $11,000,000,000. Farmers' mutual fire companies are numerous in the middle Atlantic and north central states, and in some cases are smaller in membership and in volume of insurance than is desirable. In southern states where the cost of commercial insurance is high and large percentages of farmers are uninsured,

there are few farmer-owned and farmer-controlled companies. Under some so-called perpetual policies, the amount of property insured may remain constant over long periods. Five-year terms are regarded as more desirable.

During the period 1914–35, the annual average cost of protection through mutual fire companies varied from about 23 to 32 cents per $100. About two-thirds of this cost was for losses and one-third for expenses. In some north central states annual costs were less than 20 cents per $100. Classification or rating of risks has been most common among the farm mutuals of the Pacific Coast states.

Rural fire and lightning insurance has long been established on a mutual basis in countries of continental Europe but to a less extent than in the United States. Commercial fire and lightning insurance has been a main dependence in Great Britain.

**Windstorm Insurance.**—Tornadoes and windstorms produced losses in the United States estimated at $35,000,000 annually from 1916 to 1935 In 1934 more than $3,700,000 of windstorm losses were covered by farmers' mutual windstorm companies. In the period 1900–35, operating expense varied from 3.5 to 8 9 cents per $100 insurance, an average of about 5 cents, while losses varied from 1 6 to 17.0 cents, an average of nearly 8 cents. Insurable risks include farm dwellings, most other structures, household goods, farm implements, livestock and farm products. A few companies provide that when a building falls or is materially damaged as a result of a windstorm, and fire ensues, the insurance is extended to cover the fire loss. Three-fourths of the companies in 1944 wrote policies for a five-year term, a small number for 8 and 10 years, and one-fifth wrote perpetual policies. A common practice is to write insurance at from 66⅔% to 80% of the total value of property. Since windstorm losses have been high on buildings poorly built for wind resistance, some companies classify risks and provide periodic inspection. Reserve funds of nearly 20 cents per $100 of insurance were reported in 1935, this being about half the desirable amount of reserve. About one-third of the farm windstorm companies carry reinsurance.

**Crops All-Risk Insurance.**—The first attempt at all-risk crop insurance was in Minnesota in 1899. Between 1917 and 1921 certain fire insurance companies introduced contracts for comprehensive crop-risk insurance. The first U.S. federal attempt toward crop insurance was under Title 5 of the Agricultural Adjustment act of Feb. 16, 1938. The Federal Crop Insurance corporation thus established provided all-risk yield insurance for wheat beginning in 1939 and for cotton beginning in 1942. During the 1943 crop season, about 13% of the wheat acreage and about 11% of the cotton acreage was insured, and the percentages of participating growers were about 30 and 10, respectively. The Agricultural Appropriation bill for 1943–44 provided that no additional insurance be written, but the power was restored in 1945.

The corporation failed in five successive years to collect premiums equal to indemnities paid. For the crop harvested in 1942, there was an excess of $22,000,000 of indemnities paid over premiums received. For three varieties of wheat insured, the premiums exceeded the indemnities, namely, white, hard red winter and hard red spring, but for soft red winter wheat indemnities were more than three times the premiums.

Under the crop insurance programs farmers were standing the first 25% (or 50%) loss in yield below the basic yield. In 1942 and 1943 an applicant could give a "commodity note" for the premium, which was expressed in bushels. Under this procedure the price was established at the maturity of the note, which was about harvest time.

The soviet union, under the law of July 19, 1934, developed two types of compulsory crop insurance. In addition to a specific risk insurance extended to many crops, there was provided an essentially all-risk insurance for a limited number of crops, mainly industrial crops, including cotton, tobacco and soybeans. This insurance did not cover low yield resulting from poor germination of seed and exhaustion of soil With a few exceptions, quantitative losses only and not impairment of quality, are insurable in the U.S S.R. The hazard of drought damage has been among the most difficult to cover

**Crops Hail, Frost and Flood Insurance.**—Hail insurance was begun in the United States in the 1880s among Connecticut valley tobacco growers and among farmers of North Dakota A state hail insurance department was instituted in the latter state in 1911 and the example was followed by South Dakota, Montana, Nebraska and Oklahoma. In 1919 hail risks estimated at $560,000,000 were carried by four state insurance departments, 41 mutual companies and 43 joint stock insurance companies.

High risk territory for hail damage is found also in the prairie provinces of Canada. In Saskatchewan the Municipal Hail Insurance association, organized under an act of 1912, carried $25,000,000 of risks in 1921 and 1922 The Hail Insurance district of Alberta was formed under the Municipal Hail Insurance act of 1918, and in 1919–22, $72,000,000 of risks were borne by its Hail Insurance board. These were reduced in later years.

In Europe, likewise, hail insurance has had extended use. Scottish Friendly societies are credited with having first provided hail insurance in the 1770s. In 1791 the Hail Damage society of Braunschweig, Germany, became the first continental venture In the early 1800s came French hail coverage by a society of mutual insurance. After the 1860s provisions for hail insurance were made in Russia, and later in Austria, Czechoslovakia, Denmark, Italy, Rumania, Sweden and Switzerland.

Frost insurance has been written for the protection of growers of sugar cane in Louisiana and citrus fruits in Florida and California. Insurance against fire damage to growing crops has considerable application both in North America and in Europe. The first known attempt to provide insurance against flood was in Austria in 1846. In general, flood insurance has not been successful. A limited indemnification for losses to crops and other property sustained from flood, earthquakes, windstorms, drought, etc., has been provided at public expense in Italy. The more comprehensive provisions of soviet Russia require contributions from the insured, with only specially favoured crops insured free of charge. Private associations in China have provided insurance against flood, drought and locusts.

**Livestock Insurance.**—There was a rapid growth of livestock insurance in the United States in 1919 and 1920 when meat prices were high. Thereafter such insurance fell to almost negligible amounts. Insurance of livestock in premises insured against fire and lightning is often included. Under the Farm Security administration after 1935, associations of clients were set up to insure life and property, and a veterinary group plan was adopted.

Mutual livestock insurance originated in Europe about the 13th century, primarily in Germany. France provides a leading modern example of European livestock insurance. Among 14,896 subsidized co-operative insurance and re-insurance societies in France in 1921, more than 10,000 were societies for livestock insurance. European experience has shown it to be more practical to insure large animals, such as cattle, than smaller animals such as hogs and poultry. Insurance of carcasses against condemnation by sanitary authorities has been adopted in some European countries. In Lithuania, under a law of 1938, a fund was set aside from government taxes whereby 70% of the value of livestock killed by lightning or by the collapse of buildings was payable to the farmers.

Insurance of livestock of exceptional value per head, as for racing, breeding, etc., has been widely applied in North America and Europe alike. Insurance of livestock while in transit to market is normally provided by the carrier.

**Farm Motor-Vehicle Insurance.**—Fire, theft, collision, public liability and property damage are important phases of insurance of automobiles and other motor vehicles used on farms. In 1936 a federal survey indicated that in the United States three-fourths of the farm families had automobiles and one-third of these carried automobile insurance. In New England, middle Atlantic, north central and Pacific regions, more than half were insured. There was little difference between farmers of high and of low income in the proportion of automobiles insured. The average automobile insurance premium paid by farm families was $22. There has been a lower accident risk for farm automobiles.

Farmers were maintaining less ample public liability and collision coverage. Trends after World War I were toward a higher proportion of farmers owning automobiles, trucks, tractors and other automotive items and toward a higher proportion insured. Insurance activities of farmers' organizations expanded the coverage in these fields. Under some state laws truck insurance was made practically compulsory.

Farm automobile insurance has been largely confined to commercial companies in countries outside of the United States.

**Employers' Liability Insurance.**—Farm operators with hired labourers are liable for employee accidents during time at work and when in transit to and from work, if the accidents are due to negligence of the employer. Employers' liability insurance is provided by farm mutuals and stock companies in the United States. In 1943 the annual minimum premiums charged farmers for workmen's compensation insurance and for employers' liability insurance were reduced in almost all parts of the country. Wartime use of emergency labour called for quarterly and even monthly insurance. An employers' liability contract with a reimbursement limit of $250 (or $500), for medical expense was developed for short-term employees.

**Personal Insurance.**—Members of farm families and others working on farms have need for personal insurance against loss of income or against increased outlays incident to (1) death (life insurance, burial insurance), (2) survival (old-age insurance, juvenile insurance), (3) impairment of health (accident and sickness insurance), and (4) inability to sell labour time (unemployment insurance). In areas of the United States surveyed in 1936, life insurance was held by only 43% of farm families. Many small policies had lapsed in the depression years preceding the survey. The average premium then shown was $72 a year. Among four life insurance companies showing lowest expense per $100 insurance in the United States in 1943 one was farmer-owned and farmer-controlled. In the period, 1936–41, there was a trend toward more [illegible] insurance. A 1941 survey indicated that 50% of the farm [illegible] carrying life, endowment or annuity insurance, and 11% health and accident insurance.

Protection against unemployment and against destitution in old age has been provided under national social security schemes in the United States since 1935, and in other countries for a longer period, but generally with little application to agriculture.

**AGRICULTURAL LABOURER.** An agricultural labourer is a person, male or female, employed for wages by an occupier of agricultural land. In the United States and some other countries the term "hired man" is generally used. In Scotland the term "farm-servant" is the equivalent to that of "agricultural labourer" in England where the alternative term "farm-worker" is also in common usage. Conditions of employment vary widely. The contract of service may be by the day, week, the month, the half-year or the year. Remuneration may be wholly in cash or partly in cash and partly in kind. Census definitions of agricultural labourers vary considerably from one country to another, and comparisons of the relative importance of the wage-earning force in the various countries are difficult. In a few it is less than 20% of the persons occupied in agriculture, but in the majority of developed countries, it is between 20% and 40%. In Great Britain and the Netherlands it was as high as 60% before World War II. In Great Britain the status of the farm worker after World War II was almost identical with that of the wage earner in other industries, semifeudal relics having been discountenanced by trade union influence and by statutory wage regulation. (*See* AGRICULTURAL WAGES.)

In addition to agricultural labourers permanently employed there are large numbers of men and women who are employed as casual workers. They are employed for short periods, usually at piece rates, in seasonal operations, such as corn harvesting, fruit picking, hop picking, etc. One class of casual workers may be employed most of the year at various jobs in agriculture. Another class are townsfolk unskilled in farm work who go into the fields only at certain seasons, particularly during the harvesting of fruit, potatoes, etc. Machinery in some instances greatly reduced the demand for casual labour.

**Enumeration.**—Returns collected annually by the ministry of agriculture and the department of agriculture for Scotland from all occupiers of agricultural holdings in Great Britain show that in June 1939 there were 711,232 agricultural workers of whom 600,700 were "regular workers" (54,679 women and girls) and 110,462 "casual workers" (38,535 women and girls). World War II made heavy demands on farm workers as in other industries. In 1945, the farm labour force of Great Britain totalled 785,804 persons, of whom 611,092 were "regular workers" and 174,712 were "casual workers." But the "regular" male workers were 24,742 fewer than in 1939. To handle the increased output of the war years "regular" women workers were greater than in 1939 by 35,064 and "casual" workers were 64,250 more (32,291 women and 31,959 men). These figures for 1945 do not include the members of the women's land army, which numbered about 46,000, and prisoners of war, approximately 67,800 of whom were working on the land.

The "gang" system of seasonal labour which was notorious in the early part of the 19th century declined after the Gangs act was passed in 1867 to repress its abuses. During World War II groups of labour were employed and organized by the agricultural authorities of the counties to provide a mobile reserve for farmers who found themselves unable to overtake seasonal operations or for special jobs like draining and hedging.

There is a great variety of jobs to be done on farms, but specialization of labour has not been carried very far. The "skilled" farm worker is a man capable of undertaking not one but a variety of skilled jobs. Versatility and resourcefulness are distinguishing qualities in high-grade men. There are, however, certain main classes, most of them determined by the handling of particular kinds of livestock. The decennial census enumerates horsemen, shepherds, cattlemen, tractor drivers, general labourers, but on some farms there are other titles such as pigman, poultryman, thatcher and so on, which may in most cases indicate more of a special emphasis of their work rather than an exclusive occupation.

The housing of farm workers had become by late 1946 an increasingly difficult and controversial subject. Single men were housed variously in different parts of the country. With the great mobility of modern transport the old system of "living in" with the farmer was probably being displaced gradually by the men finding lodgings in the neighbourhood. There was said to be no substantial decrease in the "bothy" and "chaumer" system (common in Scotland and north of England), but where formerly the feeding of the single men was done by the farmers' kitchens, it is now increasingly done on a contract by wives of the married workers. A married worker may be provided with a cottage by his employer and the occupation of the cottage is conditional on the job. This is known as the "tied cottage." Otherwise, the worker may occupy a house in the neighbourhood which is not "tied" to any particular farm or employer. In the case of the "tied cottage" the farmer deducts the rent from the man's wage but under the statutory wage regulations the maximum deduction is fixed. Opposition to the tied house is that if a man changes his job for any reason at all his home is also upset; it puts him more at the mercy of his employer than in the

case of a man whose house is independent of his job On the other side it is claimed that farmers need to have certain men housed close to their work and to be able to get possession of cottages for men whom they themselves employ. The situation was obviously made more acute by the general scarcity of houses in rural areas. An official report in 1937 estimated that roughly 500,000 houses in England and Wales were occupied by agricultural workers, of which 200,000 were tied cottages. In Scotland the housing of married workers in tied houses was estimated at practically 100%.

**Social Insurance.**—Agricultural workers came under the National Health Insurance Scheme from the outset in 1910 and its subsequent developments under the acts 1911–41; the Old-Age (Non-Contributory) Pensions from 1908; the Widows' and Orphans' and Age 65–70 (Contributory) Pensions under the acts 1924–43, and the Workman's Compensation acts 1925–43. They were, however, excluded entirely from the Unemployment Insurance act of 1920 which extended state unemployment insurance to industry in general. Following a report in 1935 by the Unemployment Insurance Statutory committee, a special scheme for agriculture was brought into operation in 1936.

**Organization.**—The combination of workers for the advancement of their economic interests and particularly for collective bargaining with employers was later and less effective among agricultural workers than in other trades. In England, apart from a few spasmodic local efforts, the first organized attempt to establish an agricultural trade union was made in 1872 under the leadership of Joseph Arch. A National Agricultural Labourers' union was formed which in a short time enrolled about 70.000 members. Success was not maintained and trade union activity was negligible until the following century. In 1911 the National Agricultural Labourers' and Rural Workers' union was started and by the end of 1913 had a membership of nearly 12,000. The Scottish Farm Servants' union was established about the same time. The Workers' union also included an agricultural section. A substantial growth took place during and after World War I in both England and Wales and in Scotland. The establishment of the Agricultural Wages board and its county committees in 1917 was said to give the main impetus though statutory wage regulation in agriculture was not established in Scotland until World War II. Because of the difficulties of defining a farm worker and to the number of scattered workers to whom unions can offer practically no union contact, the proportionate strength of trade union membership among agricultural workers is difficult to calculate. In 1919, it was claimed that about half the agricultural workers were enrolled in trade unions, while in 1926 the membership was said to be not more than 6%, but the former figure, if based on figures of all officially returned farm workers, was grossly exaggerated. During 1946, agricultural workers were enrolled in the National Union of Agricultural Workers, the Transport and General Workers union agricultural section (with which the former Workers' union was amalgamated) and the Scottish Farm Servants' union, which in late years had been affiliated with the Transport and General Workers' union. The estimated membership of these totalled in 1946 approximately 170,000. (J. P. Mn.; H. C. M. C.)

**United States.**—The typical farm in the United States is a family farm, with the farm operator and his family providing all or a large part of the labour. In the harvest months of heaviest farm employment there is, for the country as a whole, only one hired worker employed for each two farms. The census enumerated 6,000,000 farms in 1945; for the three years, 1944–46, the total number of hired workers employed in agriculture varied from about 1,500,000 in January to about 3,000,000 in the peak months of July to October. The January number approximates the number of year-round hired workers.

With farms increasing in size, largely as a result of mechanization, there had been a decline in the numbers of both hired workers and family workers, the latter including farm operators and members of their families working without wages. For the country as a whole the decline was relatively greater for hired workers than for family workers. Numbers of workers employed in agriculture were reported as follows by the department of agriculture:

| | 1910–14 | 1935–39 | 1946 |
|---|---|---|---|
| | 1000's | 1000's | 1000's |
| Family workers | 9,160 | 8,352 | 7,864 |
| Hired workers | 2,892 | 2,568 | 2,148 |
| Total | 12,052 | 10,920 | 10,012 |

Numbers of hired workers declined more in the corn belt than in any other area of the United States. In Iowa, Illinois, Indiana and Ohio the number in 1946 was only 47% of the 1910–14 average. In contrast, the number of hired workers in the northwestern states of Washington, Oregon and Idaho was 31% higher in 1946 than in 1910–14: in this area the number of family workers also increased, by 29% from 1910–14 to 1946.

During World War II and the immediate postwar period farmers requiring hired workers had great difficulty filling their needs, and at greatly increased wage rates The composite wage rate per month, as calculated by the department of agriculture, was $96 40 on Oct. 1, 1946, compared with an October average of $30.20 in 1935–39, and $24 76 in 1910–14.

To assist in the recruitment and placement of workers a farm labour program was set up in the extension service at the beginning of 1943. This program provided a valuable service to farmers in securing both year-round workers and the large numbers of workers needed for short periods during harvest. In the first ten months of 1945 a total of 5,724,445 placements were made in this program, the number declining to 3,752,176 in the first ten months of 1946. To supplement the workers available in the United States foreign workers were also recruited, principally in Mexico and in the West Indies The extension farm labour program also placed World War II veterans as hired hands on farms, making 32,000 such placements in 1945 and 100,000 in the first ten months of 1946.

Farm labourers in the United States were in 1946 prevailingly unorganized. During the administration of Franklin D. Roosevelt there was some increase in their organization, particularly among migratory workers. The principal aims of organized farm workers were higher wages, better living conditions and amendment of the Social Security law to include agricultural labour.

**AGRICULTURAL ORGANIZATION.** In most countries a growing realization of the weakness of the isolated farmer as a marketing unit and, again, of the dominance of industrial and commercial interests in modern legislation prompted the formation of farmers' organizations, in order to secure more adequate consideration of the position and needs of agriculture. The conditions of food scarcity brought about by World War I stimulated this movement. (*See* AGRICULTURE: A GENERAL SURVEY.)

Governments were obliged to deal collectively with the primary food producers, who on their side were forced into combinations to secure that the necessary regulations neither impeded production nor imposed an impossible burden on the farmers. Combinations for marketing are dealt with elsewhere (*see* AGRICULTURAL CO-OPERATION); the organizations here to be considered aim at uniting the farming community in order to influence legislation.

Further, since it has become clear that the status of the food producer can with difficulty be determined within the nation itself, considerable effort has been given to the formation of international associations which might be able to secure common action in the interests of agriculture. It is recognized that as regards the great staple articles of food, wheat and the other cereals, meat and dairy products, a common world price tends to be set, determined by the incidence of the exportable surpluses from the countries producing more than they consume, upon the chief open markets, *e.g.*, the United Kingdom. For example, the United States produces a certain excess of wheat beyond its requirements, which has to be exported chiefly to Europe. The price the American farmer will receive will be forced down by competition to the price obtainable in Europe less freight and

commission. This is, to take an analogy, the pressure generated by internal competition to sell, at which the safety valve blows off. The coincidence of other surpluses upon the European market or weakness in purchasing power there tends to lower the price; conversely the growth of a new demand, as from China and Japan, will enhance the price.

The tendency of commerce is generally to bring the run of prices of agricultural products, the output of which fluctuates from causes beyond control, continually down to the level caused by a surplus anywhere, a level which is on the average undesirably close to or even below the cost of production. Hence a general depression of the agricultural interest all over the world and an increasing tendency on the part of farmers to seek more remunerative occupation in industry or commerce. This is the justification for the attempts to create some international organization of farmers, however remote and impracticable common action may seem.

**National Organization.**—Examples of national organizations with legislative programs are the Union Suisse des Paysans, the National Farmers' union of England and Wales, the National Farmers' Union and Chamber of Agriculture of Scotland, and the Patrons of Husbandry (*see* GRANGE), the Farmers' Educational and Co-operative Union of America and the American Farm Bureau federation (*q.v.*) in the U.S. (*See* FARMERS' UNION.)

Perhaps the most notable agricultural organization in Europe from the point of view of influence is the Union Suisse des Paysans of which Ernst Laur was long the director. Organized in 1898, its membership includes nearly all the farmers of Switzerland.

The National Farmers' union was founded in 1908 and grew comparatively slowly until 1917, when it became necessary for agriculturists to have one organization to deal with the government in the campaign to increase food production. It is organized on a basis of county branches, each of which makes an allotted contribution to the central body. The union for Scotland was organized in 1938.

**International Organization.**—The International Institute of Agriculture (*q.v.*), as visualized by David Lubin, was created on the initiative of King Victor Emmanuel III of Italy in 1905. Its constitution was determined by treaty between the contributing states, and it was governed by a president and a permanent committee acting as the executive authority to carry out the instructions given by an assembly representative of the constituent states, sitting every two years in Rome, where the institute had its permanent home.

The representatives at the assembly and on the permanent committee were nominated by the respective governments; thus the institute was essentially a governmental organization, in which agricultural associations as such had no part. The work of the institute was of a technical character. It prepared an annual summary of the agricultural statistics of all countries and a digest of agricultural legislation; it also issued bulletins at regular intervals abstracting the papers appearing in the technical publications of the world on economic and scientific subjects connected with agriculture. The institute also convened from time to time international conferences on particular questions. In order to obtain an expression of international agricultural opinion that would be independent of governments the institute formed an association of representatives of agricultural associations of all countries, and the first meeting of this body was held in Nov. 1927. The associations invited to send representatives were, however, nominated by the governments of the respective countries.

Italy's entrance into World War II necessitated the withdrawal of the delegates representing the United Nations from the institute. With the founding of the Food and Agriculture organization of the United Nations in 1945 (*see* below), member nations of the U.N. who were also members of the International Institute of Agriculture agreed to dissolve the latter. All activities were assumed by the F.A.O., and the institute wound up its work on July 31, 1946.

The Commission Internationale d'Agriculture (later Confédération Internationale de l'Agriculture) a body founded in 1889, of which the chief task was the organization of the successive international congresses of agriculture, was eventually reconstituted in 1928 to consist of representatives of agricultural associations, not exceeding six for each country, and of co-opted members of distinction in agriculture, which latter might take part in the discussions but not vote. While the commission met twice a year in Paris, the resolutions to be communicated to governments were reserved for discussion at a conference held every second year in connection with the international congresses of agriculture.

The Food and Agriculture organization of the United Nations was created by the U.N. at the Hot Springs, Va., convention of May 1943 and was established as a specialized agency of the U.N on Oct. 16, 1945. The F.A.O., as mentioned above, took over the work of the International Institute of Agriculture, with headquarters in Rome.

[illegible])

**AGRICULTURAL POPULATION, U.S.** As defined by the U.S. census bureau prior to the 1950 census, urban territory in the U.S. included all incorporated places of 2,500 or more. This definition was expanded for the 1950 census to include suburban areas around cities of 50,000 or more, and certain unincorporated places not previously included. Under this definition, 96,440,528 persons were classified as urban (60.4% of the total) and 54,256,833 as rural (39.6%). It was estimated that under the old definition of "urban," approximately 41% of the population would have been classified as rural in 1950. In 1940 about 43.5% and in 1930 about 43.8% had been counted rural.

**AGRICULTURAL POWER AND MACHINERY** The ingenuity of man has provided the farm with power and machines to make possible the necessary crop production in spite of the demand for labour in carrying on the world's other various and complex work. When industrial developments or simple trades grew up in cities and attracted labour from the rural districts, inventors soon began to improve the means of preparing seedbeds, cultivating, harvesting and simple processing on the farm or at places near by. This development was slow at first when manufacturing was small-scale and crude. Those were the days when plows were changing from natural wood forms to shaped wood and then to metal-shod wood, to metal and finally, to polished steel; the days when reaping equipment was changing from the back-tiring sickle to the back-tiring scythe and cradle; the days when man was slowly learning to save himself or his wife by using animal power—cattle, camels, horses and mules. Man and his beasts of burden provide much of the farm power in wide areas of the world, but the period following 1830, for 100 years and more, saw a steady change toward laboursaving and efficiency in agriculture, particularly in the United States and the countries of western Europe. After 1900 the tempo of farm mechanization had been greatly accelerated not only in the countries mentioned, but in other countries, notably in the U.S.S.R. following World War I. This trend reached into Australia and New Zealand, parts of South America, and into South Africa. The tendency at first in the adoption of farm power was to use tractors for the heavy work of plowing and the crucial work of harvesting where time is of unusual importance.

In many wide parts of the world the use of power and other modern methods of farming has not gone far. This is true in much of Africa, nearly the whole of Asia, except in Siberia where Russia has developed the use of power on its collective farms, and in South and Central America except for considerable modernization of corn and small grain growing in Argentina and spotty developments in modern farming of cotton and sugar lands where large owners have introduced power and machines.

The speed with which power and machinery have changed the age-old methods of getting food and clothing from the soil and saved man from the bugbear of excessive man-hours is attested by carefully prepared statistics. Other factors than laboursaving

are, of course, recognized as resulting from the use of power and machinery—better quality of product as the result of having the work, particularly the harvest work, done at the right time; better yields resulting from precise planting and proper placing of fertilizers and more thorough harvesting; and less waste through weathering and rotting.

The tables prepared by the U.S. department of agriculture are presented as showing the hours of man labour required in growing an acre of wheat (20 bu. to the acre) at various times—by so-called hand methods in the period about 1830, by machines in 1896 and again in 1940. Not all the operations in 1830 were done by hand, of course. Horses (or probably oxen) did the plowing and harrowing and hauled the bundles of grain to the threshing floor.

Table I.—*Approximate Labour Requirements for Major Operations in the Production of One Acre of Wheat* (20 bu.)

*Hand Methods, About 1830*

| Operation | Equipment used | Operators Number | Power | | Man-labour Hours |
|---|---|---|---|---|---|
| | | | Horses Number | Tractors Number | |
| Plowing | Walking plow | 1 | 2 | | 6.7 |
| Sowing | Sack | 1 | | | 1.2 |
| Harrowing and covering seed | Brush | 1 | 2 | | 2.5 |
| Reaping, binding and shocking | Sickles | 2 | | | 20.0 |
| Hauling bundles to barn | Wagon | 2 | 2 | | 4.0 |
| Threshing and stacking straw | Flail and forks | 1 | | | 13.3 |
| Winnowing | Shovel, sheet, and measure | 3 | | | 10.0 |
| Total | | | | | 57.7 |

By 1896, according to the same source, an acre of wheat in the winter-wheat belt, where the growing of the crop was not so highly specialized as in the more strictly wheat area of the Great Plains, required only 8.8 man-hours. Table II shows the details and records an event of great significance to modern agriculture—the arrival of the farm tractors, which at this time did only threshing work.

Table II.—*Approximate Labour Requirements for Major Operations in the Production of One Acre of Wheat* (20 bu.)

*Machine Methods in Central Winter-Wheat Belt, U.S.A., 1896*

| Operation | Equipment used | Operators Number | Power | | Man-labour Hours |
|---|---|---|---|---|---|
| | | | Horses Number | Tractors Number | |
| Plowing | Two-bottom gang plow | 1 | 4 | | 2.0 |
| Sowing | Broadcast seeder | 2 | 2 | .. | .2 |
| Harrowing and covering seed | Seed harrow | 1 | 4 | .. | .3 |
| Harvesting | Binder | 1 | 3 | | .7 |
| Shocking | | 2 | .. | | 1.3 |
| Hauling bundles to thresher | Wagons | 12 | 16 | .. | 2.0 |
| Threshing and stacking straw | Thresher and forks | 7 | .. | 1 | 1.0 |
| Hauling water and fuel | Wagon and barrels | 1 | 2 | .. | .2 |
| Hauling wheat to granary | Wagons | 1 | 4 | | .9 |
| Unloading at granary | Shovels | 1 | | | .2 |
| Total | | | | | 8.8 |

Table III.—*Machine Methods in Great Plains, U.S.A., 1940* (20 bu. per acre)

(Figures for one acre)

| Operation | Equipment used | Man-labour hours |
|---|---|---|
| Plowing | 2-bottom gang (14") | 1.5 |
| Disking | 7-in. tandem disk | 0.4 |
| Harrowing | 12-ft. harrow | .2 |
| Drilling | 10-ft drill | .4 |
| Harvesting and threshing | 5-ft combine | .8 |
| Hauling to granary by truck | | .8 |
| | Tractor power | |
| Total | | 4.1 |

At the time represented in Table III showing the rise of mechanization in wheat production in the United States, the farm tractor had long been an important factor not only in grain farming in that country but in many other parts of the world—Great Britain, western Europe, Russia, South Africa, Australia, Argentina. It had become a factor in corn (maize) production and in growing even those crops that do not require such extensive acreages.

From the time agricultural engineers really began developing power machinery for field work, about 1900, the tractor and the machines drawn or pushed with it have been modified extensively—the tractor to be made more suitable for the machine and the soil, and the machines to adapt them to the tractor and the soil and to specific crops. Tractors have become progressively lighter, better suited to many field machines and to smaller farms and smaller fields—in other words, a handy source of power. In the modern agricultural communities of many countries the generation of farm boys running the farms in the 1940s knew about tractors and the tractor way of doing work from the beginning of their farming. But the tractor is not the entire change—it is the symbol of a long chain of modernization, including a procession of plows, planters, fertilizer distributors, cultivators, harvesters, loaders, storing machines (elevators), and equipment for preliminary processing, such as the cleaning and ginning of cotton and the preparation of flax fibre and other materials that are partly processed before leaving the ownership of the farmer.

Along with the rapid adoption of power for field work (drawbar power), belt work and for hauling on the highways, there was a rapid increase from 1910 on in the use of electric power on farms as well as of electric current for lighting. This growth in rural electrification was most conspicuous in Germany, the Scandinavian countries and the British Isles. However, after 1930 there was a great increase in the number of farms in the United States using electric power, in part the result of government development work. Along with the rise in the number of farms electrified came new applications of electricity such as for chicken and pig brooders and as power for hay drying. In many places there has been a great increase in the use of milking machines and other dairy equipment.

**The United States.**—In the United States, where the number of farm tractors manufactured annually increased from 4,500 in 1910 to 358,550 in 1941, the use of horses and mules decreased accordingly, the total number falling from 24,000,000 to about 12,000,000. There were about 2,000,000 tractors in the United States in 1944. A conspicuous change was in the adaptation of all kinds of field equipment for various crops to the use of mechanical power. Furthermore, there was a noticeable spread in the use of power to include more operations and crops that require special equipment. Examples of the latter are machines for planting so-called sheared sugar-beet seed (cut down so as to get rid of multiple-germ seed balls and reduce the plant thinning job) and corn picker-huskers (adapted to fields of 50 acres or more). The use of power and machinery on farms in the United States was at one time thought to mark the beginning of the end of the family-sized farm, but the size of a family-sized farm is larger than it once was (size depending on the kind of farming), and engineers and manufacturers have built machines for use on smaller and smaller farms. The small so-called handy tractors are a good example of this trend. Many improved machines are of as much benefit to family-sized and small farms as to large farms. This may be said of many planting machines and fertilizer distributors. It can also be said of much labour-saving equipment for use about the farmstead—for example, milking machines, coolers, and shop equipment such as grinders, saws and drills.

The rise in the use of power and machinery on U.S. farms is in no way better emphasized than by the fact that in practically every one of the 48 states there is a state-paid agricultural engineer as a part of the educational organization known as the extension service, whose duty is to acquaint the county agricultural agents, and through them the farmers, with the most useful new mechanical equipment and practices.

For the United States the advances in this field might well be summarized as: (1) a rapid increase in the use of power, largely internal-combustion engines and electric motors; (2) application of power to more farm operations; (3) a greater variety

of better machines; (4) machines for small farms as well as large; (5) great expansion in rural electrification; (6) improved machinery and methods for harvesting hay to cut cost of labour and improve quality; (7) great increase in self-propelled farm machines such as combine harvester threshers, and tractor pulled and operated picker-huskers and balers; (8) better planting and fertilizer distributing equipment and practices; (9) electrical equipment for farm refrigeration and quick freezing; (10) new practices in weed control, including use of machines and even burning contrivances (experimental); (11) ways of reducing draught of farm machines; (12) safety devices; (13) more durable material in machinery.

**Great Britain.**—In Great Britain, where the system of cable plowing by means of stationary steam engines which pull plows back and forth with cables wound on drums had been extensively used, the gasoline tractor increased greatly in numbers, particularly following the outbreak of World War II. The scarcity of labour for farms made greater use of power a necessity and many more tractors were built and great numbers imported from the United States. As in the United States, the tendency in the 1930s and 1940s was toward the moderate-sized or handy tractor, the one-plow or two-plow kind being much in favour. From 1939 to 1944 the number of tractors in Great Britain increased from 55,000 to 160,000.

The British, as was to be expected, applied power and new machines to the problem of getting the best returns from grass. Because of frequent rains, putting up good quality hay is difficult and the storing of grass in silos became popular with the more progressive farmers. Machines which cut the grass into short lengths and elevate it into wagons or trucks are a satisfactory means of harvesting this large-acreage crop.

British farmers, especially after the outbreak of World War II, made increased use of the grain combine—the harvester-thresher—and the use of this machine, as grain was often damp because of lack of curing, led to an increase in the use of grain driers.

Some grain harvesting in the British Isles is done by a system in which the grain is cut with a reaper and not bound in bundles, the unbound grain being elevated to a wagon and hauled to the thresher. British threshing machines not only separate the grain from the straw, but chaff, short straw, long straw and dirt are all delivered in separate piles which makes it possible to utilize the various materials to the farmer's liking. The method fits in well where the coarse materials are needed both as feed and as bedding for livestock.

Because of the high humidity, pastures in some parts of the British Isles often become choked with a growth of moss, and this has led to the use of the moss harrow in spring and early summer.

The Institute for Research in Agricultural Engineering at Oxford university, England, conducts investigations on all sorts of farm engineering problems and has a tractor-testing plant similar to the one at Lincoln, Neb., in the United States. The institute's tests have had a considerable effect on increasing the use of pneumatic tires on farm machines. Other work has had an effect in reducing the draught of plows and other implements.

By and large, the increased use of power and machinery in Great Britain in the second quarter of the 20th century has not changed the farming systems, but has made for more economical application of them and for more convenience of the farmer. Output went up gradually as the number of workers on the land went down.

**Russia.**—Russia (the U.S.S.R) was able to take over tractors and the other machines of mechanized agriculture rapidly because it overcame the disadvantages of small farms through the establishment of collective farms and systematic planning of measures and machines to be adopted over a definite period—for example, planning for a five-year period. In many important crop-producing regions of that country the topography, soils, presence of cheap fuel and the nature of the main crop were such as to invite the rapid development of tractor farming. Men were trained to the new farm form in one generation. By 1940 a large part of the farming of the U.S.S.R. was done on collective farms or *sovkhos* and machinery is the heart of these farms. These collectives consist of small peasant farms amalgamated for more efficient and economical operation. The medium-sized and small collectives get their machines as they need them from the state tractor stations. Large state farms have their own machines.

A decade before the outbreak of World War II large tractor and harvester-thresher plants in Russia had attained a considerable output. Among these was a large tractor plant at Stalingrad and the combine-harvester plant at Saratov in the lower Volga region. Although farm implements were made in Russia before 1914, no tractors or combines had been made there. These machines imported at first and then made at home were the outstanding development in the mechanization of Russian agriculture. They have to do mostly, of course, with the production of wheat and other small grains, but tractors, especially, are the foundation of economical seedbed preparation and harvesting of various other crops to a greater or lesser extent, depending upon the accessory machines available for the particular crop. Modern machinery has been adapted extensively for cotton production, including trials of mechanical pickers and the establishment of gins with [illegible] equipment and hydraulic presses. The growing of [illegible] has also been modernized through the use of special machinery as well as tractors and modern plows. There was a strong tendency after 1926 to try out all new developments in farm machinery and to develop new ones through experiment.

**Germany.**—Germany's variety of agricultural machinery at the beginning of World War II is shown by the machines listed as of considerable number in that country's census of May 1939. The list includes more than 1,800,000 electric motors, two-thirds of them 1 to 6 h.p., 11,755 steam engines, more than 200,000 gasoline and oil engines, nearly 70,000 tractors. There were large numbers of motor mowers, choppers, seeders, fertilizer distributors, cultivators, winnowers, harvesting machines, potato pickers, threshers, forage cutters and wagons with rubber tires.

The Germans found a strong appeal in tractors (mostly small ones) powered commonly by diesel or semi-diesel engines, not particularly because of the saving in labour, but because of the need to conserve as much of the crop land as possible for growing the kinds of crops needed for human food. Every horse replaced by mechanical power meant 3 to 5 acres of land available for growing crops. Tractors and trucks were much used for transportation from the farm to market.

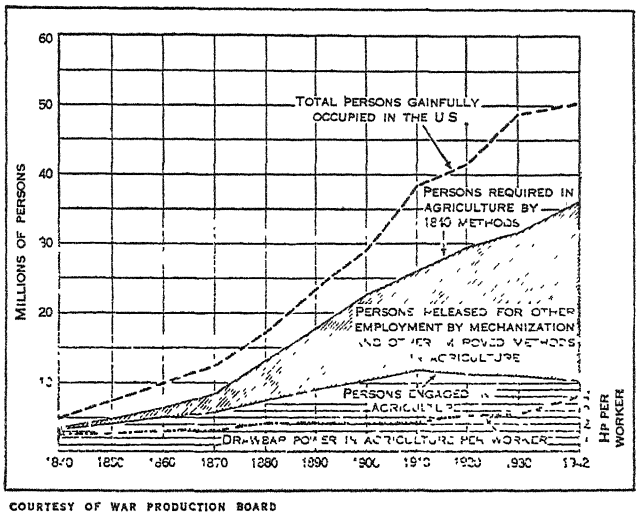
As in some other European countries and in Great Britain, farm machinery in Germany was designed to bring the farmer that little additional yield that is so much appreciated where land is none too plentiful. The row cultivation of wheat in Germany is an example, also the extreme care given to accuracy in drills for planting grain.

In Germany before World War II almost 100% of its farms were reported to have electric power. One reason for this wide distribution is the fact that these farmers live in villages and can hook up to electric lines easily and at low expense. On the other hand, they are not said to be heavy users of current.

In Germany considerable study was given to conserving and spreading barnyard manure, the solid and liquid parts often being handled separately, a tank for the latter.

**France.**—France has long been a country of farms made up of small scattered patches so that power machinery has not made the headway it has in Great Britain, Germany and Russia. The French, however, have been noted for good draught horses and have loved and tended their soil, saving manure carefully and hauling it in carts and tanks for distribution on the land. Small tractors made some headway, but it is not to be compared with the progress in the countries mentioned above. However, much attention was given to spraying and dusting machinery, largely for protection of fruit and vegetable crops, and, to some extent, to machines for placement of commercial fertilizer.

As might be expected, the limitations on the application of heavy machinery and the use of tractor power tended to keep down any large development of farm machinery manufacturing in France. Agricultural engineers studying French farming in the period just before World War II reported the farmers much in-



terested in mary new machines developed in the United States, particularly in the lighter equipment, but very little new machinery was bought. In that period France showed a growing use of electric power by farmers, but not to the extent noted in many other European countries and in England.

Before World War II France's ministry of agriculture maintained the Central Agricultural Machinery Testing station at Paris, principally for the study of physical-mechanical characteristics of the soil and to demonstrate the quality of tractors and other machines.

**South Africa, Australia, New Zealand and Argentina.**—In South Africa, Australia, New Zealand and Argentina there have been trends toward wider use of farm machinery. Wherever petroleum fuels are expensive and upkeep of horses relatively low, as in Argentina, there is a strong tendency for farmers to keep to animal power. In all these countries what mechanical power there was on farms was used mostly for seedbed preparation and grain harvesting. In New Zealand the importance of the dairy industry stimulated the use of dairy machinery and equipment.

**Africa.**—In Africa (except South Africa), from the valley of the Nile through practically the entire continent, the raising of crops is a series of primitive operations with very simple tools and poorly developed work animals. For the most of Asia, the same can be said for all the crops—cotton, rice, etc. In some areas in the far east where U.S. or European influences have been at work there has been some tendency toward mechanization and organization for more efficient production, as in the production of sugar cane, abaca (Manila hemp) and rubber. But, by and large, hand labour is the dominant factor since it is cheap and has long been accustomed to the crops.

**Machine Influence on Quality of Work and on Product.**—With machines and power available farmers soon found that not only could they do more work, and usually do it more economically, but that they could do a better quality of work. For example, plowing could be done deeper and even in the more difficult soils with a smooth steel mouldboard of proper design

COURTESY OF WAR PRODUCTION BOARD

FIG. 1.—EFFECT OF MECHANIZATION AND OTHER IMPROVED METHODS ON THE NUMBER OF PERSONS REQUIRED IN AGRICULTURE, 1840-1942

and a good margin of power. The importance of this power advantage is shown when it is necessary to plow under a heavy growth of rye or some legume crop for soil improvement. Farmers with relatively lightweight work animals find it difficult or even impossible to do such work in a way to leave the growth sufficiently covered with soil. On the other hand, with adequate mechanical or animal power, it is possible to do much better work and, what is more, the job may be finished in a favourable time. When it is possible to harrow the soil immediately after it has been turned by the plow by means of a harrow drawn behind, the use of that extra power produces a better seedbed more quickly and more easily. By using accurate planters and cultivators designed to fit the standard spaces properly, this work can be done with the minimum damage to the growing crop and the maximum of weed control, considering the time that can be spent on it. Modern harvesting machines have been adapted to all sorts of crops, and can be adjusted so as to do the minimum of damage to grain, potatoes and other products. Even the relatively simple factor of the cleaning of grain such as wheat—keeping out pieces of stalks, leaves, weed seeds and broken pieces of grain—is important in insuring a lower moisture content and in reducing insect infestation.

Planting machines insure more accurate placing as to depth in the soil, and as to space between rows and between seeds, all of these factors important in the development of plants and in proper cultivation and harvesting. In the period after 1930 great attention was given to the accurate placement of fertilizers for row crops, particularly in the United States. This was found a means of doing much better fertilization work, producing better yields, often at a saving in plant food, commonly producing a better quality crop. Modern spraying and dusting equipment not only saves fruits and vegetables and sometimes other crops from the ravages of insects and fungi, but similar methods and equipment are used for other purposes which also improve yield and quality. In the 1940s there was developed in the United States a method of spraying maturing apples and pears on the trees with certain highly diluted hormones which prevent preharvest dropping of the fruit. This reduces the percentage of damaged fruit and effects an economy in picking, as in treated orchards it is unnecessary to shift workers from one part of an orchard to another to pick from trees that have begun to lose fruit. In this same period devices for applying chemicals in vapour form in the soil to kill destructive nematodes were developed.

It may be well to mention also the development of a so-called aerosol "bomb" for use in combating insects by diffusing various insecticides widely and easily through use of a highly volatile chemical confined in a steel cartridge. These "bombs," equipped with handy valve releases, were widely used by the fighting forces on various fronts in World War II as a means of destroying flies, mosquitoes and other insects dangerous to health. The method is widely used to insure the eradication of insects in aeroplanes that might carry the pests into countries that had been free of them. By 1944 experimental work on this method in the United States was directed to the possibilities of effective use in garden and field.

Most machines that tend to make crops grow better and with less interference from various factors contribute an improvement in quality. Other machines—beyond the harvesting machines—permit a better utilization of various products. For instance, feed grinders, silage cutters and shredders increase the feeding value of roughages and other feeds. The manure spreader (and the even more modern manure loader) makes possible the better utilization of barnyard manure.

Such processing machinery as cotton gins and accessory equipment including driers and cleaners are necessary to retain whatever good qualities the fibre had when picked. Flax and hemp processing machines are of similar importance to growers of these crops.

Machines of great variety have been developed to make farm products attractive to animals, as feed, or to people who buy them on the markets. Hay is put up in such a way with driers and grinders as to keep the maximum of palatability. Citrus fruits are gassed in chambers to bring out a uniform characteristic orange or yellow colour that may have been masked by green because of conditions in the orchard. Nuts are sometimes coloured and polished to give them a uniform, pleasing appearance.

Machines have had an interesting and indirect effect on crops that is also of high economic importance. The strong demand from farmers for more and more machines and ever more efficient ones led the plant breeders and engineers to a kind of collaboration that is yielding good results in plants and machines better fitted to each other. A few examples will suffice: hybrid corn (maize) has been so bred that the height of the stalks is uniform and the ears are at uniform height, facilitating harvest with the

mechanical picker-husker. Another characteristic accentuated by the plant breeders is the tendency of the plant not to go down easily in the wind thus making it hard to harvest.

The strong stalks bred into many varieties of wheat and other small grains have become popular in many parts of the world because they do not "lodge" or crinkle down readily and thus cause heavy losses of grain the harvester fails to catch.

In the southwestern United States in the somewhat arid plains country plant breeders have adapted grain sorghums to mechanical harvesting machines by creating much shorter or dwarf varieties with upstanding seed heads to take the place of those that curved over.

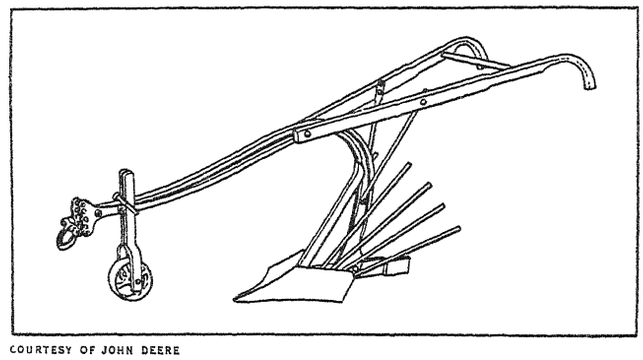
Such changes make for economy in harvesting and better quality in most instances.

The effect of the machine on quality often goes far beyond the immediate effect. For example, a corn (maize) harvester, that is a picker-husker, may be kept in good adjustment or may get out of adjustment and put much trash such as husks, silks and loose kernels in the wagon with the ears. This accumulation interferes with ventilation in the crib and may cause a heavy spoilage loss, especially in seasons when the grain has not matured well.

The use of machines for the betterment of the quality of work has gone so far in some areas as to tax the credulity of persons in other areas where mechanization has received small attention For example, in California a great part of the commercial rice crop is sown from aeroplanes Formerly the fields were planted with ground machines and later flooded as a means of watering and controlling weeds, and the fields drained before harvest. A later technique is to flood the fields early to prevent weed growth, then sow the seed from the aeroplane into the water and then, as before, drain the field for harvesting

The new method saves labour and practically eliminates the weed competition. Not only is the work better, but the crop harvested is better. Planes are often used for dusting cotton and trees with insecticides.

**Economics of Farm Machinery.**—At no stage in the development of farm machinery and mechanical methods has it been possible for all farmers to use the machines of their time economically. It is even less so (1944) as may be seen readily when reflection is given to such practices as the use of planes for planting or for fighting pests. However, more and more kinds and sizes of farm machines are made available to small farmers and in some places the use of machines or of machines and operators has been made available at a price. In parts of the United States cotton belt men do custom aeroplane dusting of cotton for planters of an area.



Horse-drawn planting machines, such as corn planters and bean planters, that were just pushing the hand planters out of use in commercial farming at the end of the 1890s are found everywhere in the western world and many of them have become multiple-row planters drawn by tractors. Farmers in the more progressive farming regions commonly have steel plows. These have spread over the world after about 1840. Because it slipped through the soil more easily—that is, "scoured" well—the draught of the steel plow was less and made farming easier for man and beast. For the farmer it was easier physically and economically. Mechanical improvements in farming have been frequent reductions in draught. Plow improvements of this nature continue. In the second quarter of the 20th century there were improvements in the plow that tended to reduce draught, changes in the curve of the steel plow was less and made farming easier for man and plow design to reduce clogging with trash; new coulters and jointers that could pass obstructions with less difficulty. Then rolling resistance on scores of farm implements, including the tractor itself, was reduced through the application to them of pneumatic tires, better lubrication and construction materials also have done their parts in reducing friction and, therefore, draught.

Practically everywhere, except possibly in primitive areas, there is evidence that the economy of the machine has pulled it out in front. In some instances it may be far from the latest development, but the farmer is feeling his way, balancing steel and brawn. The size of the individual farm and the type of farming are important determining factors. A man who raises a small acreage of berries will not use much machinery, but he might have a small tractor and in some localities he would most certainly have a truck for marketing and for hauling supplies. A dairy farmer with a dozen or more cows would frequently be found to have a milking machine, maybe with more than one unit, possibly a cream separator, almost certainly, in some countries, a manure spreader, haying machinery, and if he is right out in front in a rainy country (in 1945) he would have a hay drier in his barn.

It has become generally recognized in Europe and the United States that electrically operated tools are an economy for electric current has become widely available at reasonable rates. Sharp tools save time and improve the quality of work With an electric grinder a farmer keeps his tools in better condition with a smaller expenditure of time.

As they have become better acquainted with machines, farmers of various countries have been less prone to overinvest in such equipment. Machines must not lie idle too much. Therefore, they must be adaptable enough for various jobs or be used jointly in the community unless farms are large So, before buying a machine a farmer must assure himself that he has at least the minimum amount of work that would justify the investment.

The potato crop may be used to illustrate how a farmer might proceed under different conditions: the cheapest way to dig a small patch of potatoes is with a fork; if the area in the crop is an acre or so the farmer would likely make a good return on money invested in a simple potato plow, while a larger area

COURTESY OF JOHN DEERE

FIG. 2.—HORSE-DRAWN WALKING POTATO DIGGER

This model is particularly suitable for harvesting sweet potatoes. The rod mouldboards free potatoes from dirt and drop them on the ground. Gauge wheel regulates depth

would justify purchase of a more complex machine But the use of machinery involves consideration of factors other than relative cost of the operation in comparison with the cost by other methods. The speed with which the work can be done, especially when the state of the weather and the possibility of its continuance or change are considerations, is of primary importance even though the value is hard to measure. The study of farm cost accounting has been of help in a better understanding of these problems.

As machines have been designed to serve farmers better, their use has increased, and the size of farms and the improved land in them has become greater. In the United States, where the use of farm machinery has shown perhaps the greatest increase, the average acreage of improved land per agricultural worker went from 23 1 in 1880 to 38.4 in 1940; and the value of agricultural implements and machinery per agricultural worker went from $45.74 in 1870 to $365.81 in 1940.

Using the estimates of the department of labour (U.S.) for nine important crops (barley, corn, cotton, hay, oats, potatoes, rice, rye, wheat) and comparing the machine methods of about 1895 with the hand methods of earlier times H. W. Quaintance (*The Influence of Farm Machinery on Production and Labour*) states: "Taking the percent of labour saved as indicating the average proportion of these crops due to the use of machinery, it appears that the quantity of products is almost five times as great, per unit of labour, as it formerly was." This suggests how ma-

chinery has enabled agriculture to supply labour to the industrial cities and for commercial activities and still increase the output, as was suggested in the introduction to this article After an extensive study and presentation of data on 15 crops (barley, broom corn, corn, cotton, hay, oats, onions, peas, potatoes, rice, rye, sugar cane, sweet potatoes, tobacco, wheat) grown in the United States, the same author says: "Surely it will not be too much to say that during the last half of the 19th century the cost of production[1] of these crops was reduced by one half." There is ample evidence that the influence of machinery in effecting economies in production costs has gone on at least unabated after 1895. In 1940 figures available in the U S. department of agriculture indicated man-hour requirements per acre as follows, under highly mechanized conditions except in cotton: corn 5 1, wheat 4 1; hay 3 5; cotton 73 0. Cotton felt mechanization less than the other major crops.

**Other Effects of Machinery.**—Beyond doubt the wide adoption of farm machinery has had much more than economic effects Farmers, and particularly young people on farms, give great consideration to the convenience of machinery, to the fact that it does away with much drudgery and dignifies the work perhaps as much as scientific knowledge of the problems of the farm, and as much as skill in the performance of hand work. More often than not the use of machines leads to a better quality of work. A simple illustration will serve to explain one factor in this better quality. A man sharpening the knife of a mowing machine with a power grinder is much more likely to make all the sections sharp than if he were doing the work with a grindstone operated by himself with a treadle. Farmers can plant crops much better with an automatic planter both from the standpoint of the requirements of the crop itself and from the standpoint of the farmers' problems in caring for it and harvesting it. Modern machines and methods used on almost any of the important crops—wheat, maize, sugar beets, potatoes—could be used to illustrate the point. Here economics and the more elusive factors are on common ground.

The introduction of improved farm machinery frequently met with resistance from those who expected bad effects on employment, and at times active resistance developed. When early wheat harvesters (binders) were introduced in the developing wheat belt of the United States many of the machines were burned or damaged in other ways by worried farm hands. These machines, and the still more effective ones that have succeeded them and each other, resulted in wheat production greater than ever known before and were one of the important factors in creating a higher standard of living and in making food production more readily adjustable to meet emergencies.

At times men supposed that the introduction of farm machinery led to falling rural population, but there is evidence that in many instances the invention and introduction of labour-saving machinery for the farm followed the draining of labour away from the land. As an example, self-binding grain harvesters were invented and developed by more than one man at about the same time when the rapid increase in industrial activity lured an ever rising stream of labour from the fields. It was not railroads alone that were responsible for the rapid settlement of great agricultural areas in the United States, Canada and Australia during the 19th century; improved farm machines and implements had much to do with it. Without the machinery much of the land cropped in these areas would have been used for grazing or for timber.

The more machines are used for farming, the more skilled the workers become and the higher the wages that can be paid them. A demand for skill and a desire to acquire it tend to improve the quality of the rural population.

Although automatic equipment and higher quality tools are made in sizes and at costs that make them suited to many small and medium sized farms as well as large ones, there has been a decided tendency for the use of farm machinery, and more convenient power to increase the size of farms. In the northern part of the Mississippi valley where more machinery is used than in any other region of general farming the improved land per farm has steadily increased after 1850. In regions where general farming is practised but where machinery has not been used so much, the cultivated acreage has not increased so rapidly, and in some areas farms have even become smaller. In some instances, of course, such a tendency might be explained on the basis of a change in type of farming, such as from general or livestock to truck, because of a new market, for example, in a rising industrial area.

If the total investment in all farm property in the United States is considered, the increase after 1850 has been much greater in the farming areas in which machinery is widely used Land is the largest item in farm valuation, but its value depends to an extent upon the means at hand for making it productive. Many factors enter into increases in value, but the reduced costs made possible through machinery should always be kept in mind.

There is scarcely a farm operation in the more progressive regions that does not require less drudgery than it required, say, in 1880, or in 1900, or even in 1910, and in some instances, 1920 One farm operation that had drudgery or "stoop labour" taken away from it after 1920 was the thinning of sugar beets. To mention a few other operations that have gradually lost much of the strain and monotony over the years, where machinery has been used, there are milking, corn cutting, haying, plowing harrowing all the operations done with tractors and many of those done with engines and electric motors. Most farmers are, perhaps, as busy as their grandfathers, but they work more with their heads and their skills than with biceps and backs, and they work to the better advantage of themselves and society. In 1800 most nations had to have a large proportion of the people working on farms to provide themselves and the small industrial and business groups with food, clothing and a few other materials. In the second quarter of the 20th century an active industrial-agricultural country such as the United States had less than one-fourth of its population engaged in farming and nevertheless had farm products for export. It did, however, buy some farm products from other parts of the world—rubber, waxes, coarse fibres, etc

There is primitive farming even in modern times, some of it here and there in the most progressive agricultural countries, but modern farming is a relatively complex business even though frequently highly specialized. The first-class farmer, with many machines and exacting requirements as to breeds, varieties and mechanical and biological processes, has exchanged drudgery for application and intensity of mental effort and still has much physical labour in his lot. But he and his wife and children have a higher standard of living—more conveniences, better schooling, greater opportunities for reading and for carrying on other cultural activities. In other words, they produce more and get more, at least in many ways.

**Classification.**—Types, kinds and sizes of agricultural machinery and implements form a complex subject. Agricultural conditions into which machinery must fit vary widely between the one-horse farms found in many countries (even the most progressive), and the great wheat ranches of Canada and the United States; the operation of a hill farm varies from that of a rich valley corn farm, and the latter, in turn, is vastly different from a citrus fruit ranch. Differences in size of farms, in size of fields, in kinds of crops grown, and in the kind and size of power units most economical or practical—all cause variation in type and size of machine or implement. For a small field, one can buy a one-horse or one-mule implement for a very few dollars, or for a great plantation one may buy a special harvester which costs several thousand dollars. Because of the wide variation in soil types some large manufacturers find it necessary to make more than 100 different shapes and kinds of mouldboards for plows in addition to the disk type of plow which is demanded in very hard, in very fluffy or in very sticky soils. Land values have some influence. Then, last but not least, the human equation enters; differences in peoples and in regional customs add complication. The farm labourer of low mental calibre and of little mechanical skill requires a smaller, simpler implement than the skilled oper-

[1] Cost of production here is based on cost of labour and does not include differences in [illegible] hand and machine methods. This discrepancy, if it seems [illegible] y the fact that labour by hand methods [illegible] at the rate [illegible] machine methods it is con[illegible] the [illegible] of the higher wages current about 1895.

ator who commands a tractor hauling a combination of implements which performs two or three operations in one trip over the ground.

Space does not permit description of all kinds of agricultural machines and implements Fortunately, however, the subject lends itself to classification according to the purpose of the machine. Most of the agricultural machines, implements and tools used by farmers may be classified according to purpose. The list includes only those items considered part of the business of raising or making agricultural products, up to the moment those products are sold out of the farmer's ownership. It does not include the strictly household conveniences, devices and utilities which are becoming so widely adapted to assist the housewife and to enable the farmer and his family to enjoy more the art of living.

*Machines and Implements for the Reclamation, Maintenance or Improvement of Land:* stump pullers, pilers; brush breakers, cutters, power brush and tree saws; burners; open ditch, tile ditch and mole ditch machines; land drain cleaners; land levellers; terracing scrapers, bulldozers, graders, moss harrows; irrigation pumps, land planes (for levelling fields for irrigation), sprinklers water controls, ditchers; sub-soilers; limestone crushers; lime and fertilizer distributors (artificial manure distributors); manure loaders, lifters, muck grab spreaders; straw spreaders; stone pickers

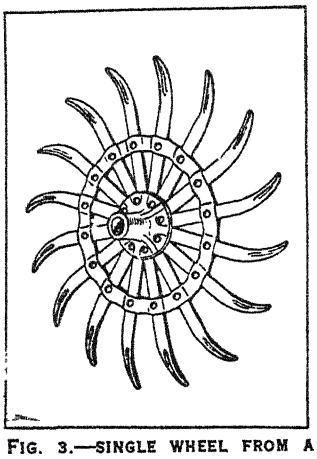
*Machines and Implements for Seedbed Preparation:* mouldboard, disk and polydisk plows; lea, sod, stubble breaking plows, drags; spike-tooth, spring-tooth, chain, zigzag disk and special harrows; smoothers and pulverizers; plain, corrugated and bar rollers; surface and subsurface packers; clod crushers; rotary, gyro and special tillers; sweeps; listers; ridge busters; stalk cutters, shavers; cotton stalk choppers; stubble diggers, pulverizers; markers.

*Machines and Implements for Seed Preparation:* fanning mills; grain, pea, bean, cottonseed, peanut, flax, onion set, rice, potato and corn cleaners, graders and sorters; seed scarifiers; sugar-beet seed slicers; seed dusters (for fungicides); seed testers; seed stringers; seed driers; tippers (for use in shelling seed corn); potato cutters.

*Machines and Implements for Seeding and Planting:* broadcasters, broadcast sowing machinery; grain, beet, grass and garden seed, bean, pea, corn (small grain), onion and rice drills; corn, cotton, beet, potato, pea, bean, onion and peanut planters; transplanters; seeders, wheelbarrow seeders; markers; lister-planters; fertilizing attachments.

*Machines and Implements for Cultivating:* corn, beet, cotton, potato, sugar-cane, vineyard, orchard and garden cultivators; celery, potato and tobacco hillers; drags; spike-tooth, spring-tooth and disk harrows; weeders; rotary hoes; crust breakers; ridgers; renovators; sweeps; root blockers; cotton scrapers, choppers; thinners.

*Machines and Implements for Harvesting:* mowers; tedders; "flop-over," dump and side-delivery rakes; "bull" and sweep rakes; hay, shock, bundle and cane loaders; crop collectors; stacking elevators, stackers; bunchers; windrowers, straw and hay balers, pickup balers, roller balers; reapers; grain and corn binders; grain and corn headers; header-binders; combination harvester-threshers; corn, cotton, potato, peanut and fruit pickers; corn picker-huskers; flax pullers, cleaners, tow shakers; grass cutter-chopper-loaders (for ensilage); root and plant lifters; potato and peanut diggers; root toppers; bean, pea, beet, celery, grass seed, spinach and onion harvesters; field ensilage harvesters; seed and cotton strippers; sugar-cane cutters, harvesters; corn and hemp cutters; shock compressors, movers, sweeps; huskers; milking machines; wool clippers; tree fellers.



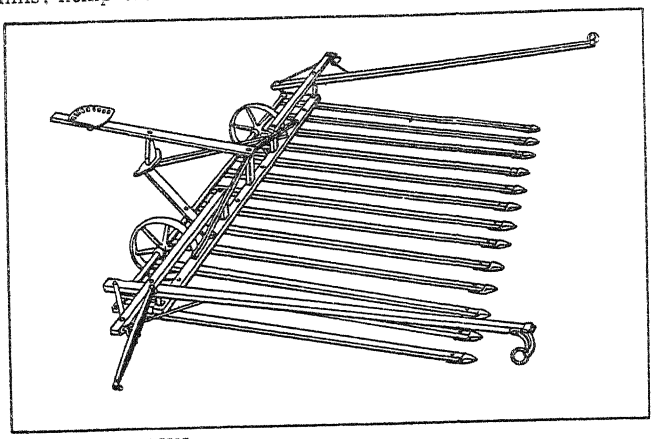


FIG. 3.—SINGLE WHEEL FROM A TRACTOR-DRAWN ROTARY HOE

The rotary hoe is used for early cultivation of all kinds of row crops, pulverizing the top soil and tearing out weeds. Each section of the hoe cultivates one row and is composed of fourteen 20½ in. wheels

*Machines for Preparing Products for Market:* grain, pea, bean, peanut and rice threshers and cleaners; alfalfa, clover, almond bean, pea, grain and rice hullers; grain, pea, bean, cottonseed peanut, onion set, rice, potato, corn, berry and fruit cleaners, graders and sorters; cotton gins and presses; balers; produce washers; produce waxers; grain polishers; corn, peanut, rice and popcorn shellers; vegetable bunchers; cream separators; milk emulsifiers, pasteurizers, sterilizers, irradiators; milk coolers, aerators; churns; butter workers; bottling machines; cheese and lard presses; sugar, fruit, sorghum and syrup evaporators; honey extractors; berry and fruit crushers; cider and juice mills, presses, extractors; bleachers; pitters; parers; sugar-cane and sorghum mills; hemp breakers and cleaners; saw mills; baggers; weighers

COURTESY OF JOHN DEERE

FIG. 4.—HORSE-DRAWN TRUSS-FRAME RAKE

*Machines for Feed Preparation and Feeding:* cutting boxes, ensilage and fodder cutters; feed mills (including hammer mills), grinders, cake breakers, mealers; roughage mealers; feed mixers, shredders; root and vegetable cutters, pulpers; feed cookers, stock feeders; bone cutters; corn and cob crushers; silo packers

*Machines and Implements for Combatting Crop Enemies:* row crop sprayers, tower sprayers, aerosol "bomb" (experimental in 1944) sprayers using liquified gases in steel cartridges as a means of propelling the insecticide or fumicide in extremely fine particles; field burners; flamers; stubble pulverizers; stalk crushers (for killing larvae that might otherwise survive in waste material); insect sweeps, poison bait spreaders, catchers, traps; tobacco bed burners; seed treaters; smut cleaners; fumigators; soil fumigators for nematode control.

*Machines, Implements and Conveyances for Transportation:* automobiles; motor trucks; wagons; carriages; horse and hand carts; sleighs; bobs; stone boats; wheelbarrows; farm, wagon, log, lumber, header and sugar-cane gears; racks and barge boxes; hay carriers, forks, slings; blowers; grain dumps, elevators; car loaders; feed and litter carriers.

*Power, Light and Heat Generators:* gas, gasoline, paraffin, distillate, kerosene, hot air and steam engines; steam and internal combustion tractors; boilers; windmills; turbines; water wheels; hydraulic rams; tread mills; power sweeps; electric motors, dynamos, generators; lighting plants; containers for compressed illuminating gas (bottled gas); tank heaters.

*Miscellaneous Machines, Implements and Tools:* incubators and brooders; disk and knife grinders; pumps and pump jacks; hay knives and hooks; hand hoes, mattocks, rakes, shovels, forks; corn, cane, tobacco and cabbage knives; pruning and grafting hooks, knives, shears and saws; fence stretchers; hog rubs; post-hole diggers, augers; lifting jacks; animal pokes and leads; dehorners; poultry debeakers to prevent birds injuring each other; horse and cattle clippers; grooming machines; milk and cream testers; utensil washers, sterilizers; scales; ladders; hand tools

and machines for wood and iron work. (*See* TILLAGE MACHINERY; DAIRY MACHINERY AND EQUIPMENT; HARVESTING MACHINERY; PROCESSING MACHINERY. Also such articles as SHEEP SHEARING MACHINES; TRACTORS; DRAINAGE OF LAND; etc.)

## HISTORY

From pictorial and other ancient scraps of evidence it seems certain that in very early times man used devices for making the soil more productive and the struggle for food and clothing easier. It is reasonably safe to say that once started on this road of improvement through invention and planning, the chain of change was never broken up to 1945, with agriculture feeding, clothing and providing materials for various purposes for more than 2,000,000,000 persons.

Studies of ancient civilizations in many parts of the world, including some regions of Central and South America, indicate cultivation of the land was going on hundreds of years B.C., even 1,000 years or more B.C. in Egypt and China. Such dates could be put much farther back on the basis of what it is certain men must have observed when they began gathering grains, fruits and roots to provide some degree of food security beyond the day or the season.

The first soil working implements very probably were the crude pieces of wood that provided the idea for shaping such chance pieces into the first hoes; the first rake very likely was a leafless branch of a tree with stiff twigs. When man had a hoe he really had his first plow; and when he had a wisp of brush for a rake he had his first harrow. Brush harrows are still used, and not too badly either, when the branches are fitted into a rigid frame or holder. Harvesting at first was simple pulling and picking—and it is really surprising how much of many crops is still pulled and picked and forked by hand in countries where complicated farm machines are common. Since the earliest cultivated crops are supposed to have been cereals and pulse (that is beans and peas and things of that sort), a very early improvement was the sickle. Some sickles in ancient Egypt were made of flint blades in a wooden handle. Later, but still near 1,000 years B.C., the men of the Nile valley used bronze to make the counterpart of the hand sickle. In those days Egyptian grain was trodden out on the threshing floor by animals just as it is even today in near-by Ethiopia and in primitive places in other parts of the world. Wheat and other grains and seeds were winnowed by casting into the wind.

Engineers who have studied the development of agricultural machinery and power generally consider that the first great mechanical advance in farming was the evolution of the plow from the hoe. It became not only an implement for preparing the seedbed and controlling weeds, but a means of covering seed, cultivating the plants, providing drains, building terraces to control erosion and even grew into a harvesting machine for digging such crops as potatoes and sugar beets. Plows were used in ancient Egypt. They marked a great advance in the use of beasts of burden and must soon have stimulated man to begin the long and slow job of breeding up the draught ox and the draught horse, the really great power sources on the land until the advent of the tractor which even in the middle of the 20th century does only a small proportion of the world's field work except in some of the western nations.

By Roman times a primitive ridging plow had been evolved by use of a device similar to the modern double mouldboard. Pliny, the elder, in the first century wrote of a wheel plow, but such plows were not common until much later. He had heard of the use in Gaul of a harvesting machine pushed ahead of oxen for heading or stripping grain. Such machines and a combined plow and drill, invented still earlier in Mesopotamia gave way before the barbarian invasions of these more civilized regions, and mechanical progress in agriculture during the middle ages and until after the Renaissance. But apparently there were small changes from time to time even in that period. In 1523 in England Sir Anthony Fitzherbert's *Book of Husbandry* mentioned plows of different types in different districts and indicated the need for different designs for the various soils in order to cut down draught. By then hand tools had been nicely designed and many of them were much like those of modern times except as to material. By 1600 more elaborate farm implements were appearing in Europe and English books of the day discussed new ways of planting grain. In 1730 Jethro Tull, of England, renowned for his developments in horse-hoeing husbandry, made a seed drill which was really workable and marked the beginning of a new day in the planting of small grains and many other seeds.

In Tull's century plowing matches began in Britain and competitions in the use of drills and horse-hoes. These activities were typical of the lively thought on ways and means of improving farming and easing the load on human shoulders. The tempo of tool improvement has continued to rise ever since. Tull opened the floodgates of farm machinery invention. It was significant that this opening was at the time when the American colonies were beginning to realize what might be done in the new land with better machines and stronger work animals. They began improving oxen and horses as the British and Europeans already were doing, and Americans began working on the plow. Eli Whitney before the end of the 18th century had devised the nucleus of the modern cotton gin. The whole western world was in this same state of mind about agriculture. India had long had a hand cotton gin, the chirka, but the east had not been in the same state of mind about farming. This state of mind, which encompassed far more than agriculture, led to the steam engine, the internal-combustion engine, traction engines, tractors, electricity, milking machines, self-binders, combine harvester-threshers, manure spreaders, grass harvesters, aeroplanes (used for dusting crops with insecticides and even for planting), and whole sets of mechanically operated machines.

**The Steam Engine.**—Even by the opening of the 19th century developments had gone far enough to justify the term "agricultural machinery." Strangely enough to present-day farmers, there was a threshing machine before there was a steam engine. The first workable threshing machine came late in the 18th century and was driven by water or wind power, sometimes by horse labour and later by steam. But steam was not much used in agriculture until after 1830. Then in England a system was devised whereby one or two engines were used to draw multifurrow plows, by means of cables, backwards and forwards across the field. The system of double-engined steam plowing was well established by 1850. Then other heavy implements were added such as the cultivator and mole plow. Then steam threshing was popular and steam engines were used to some extent to run other barn machinery. But for the most part the development of machinery on the farm owes little directly to steam. However, in the early part of the 20th century lightweight steam tractors were used in England for the direct pulling of plows and to some extent also in other countries.

The mowing machine and the self-binder, the tedder and swath turner, the drill, the potato digger, chaffcutters and root cutters all were developed in the first instance for horse or manual labour, though doubtless receiving a fresh stimulus from the general mechanization of industry applied to the farm and the still greater stimulus arising from a shortage of farm labour.

**The Internal-combustion Engine.**—An important practical contribution to the mechanization of the farm came from the invention of the internal-combustion engine. Used first of all to drive stationary machinery, as chaffcutters, root cutters, and corn mills in the barn, in the second decade of the 20th century the internal-combustion engine also made headway as a source of power for field operations. Steam engines, though widely used for traction on the road, suffered the disadvantage of being heavy for use on the land for the direct haulage of machinery and implements; it was not until the internal-combustion engine had been perfected that agricultural tractors made their appearance in any number.

This type of tractor has (1945) an established position on the farm on both sides of the Atlantic; it supplies power for plowing, cultivating and harvesting; it can both drive and haul the threshing machine, and there can be no doubt it contains the promise of still further usefulness. The practice of mole draining,

for example, was greatly stimulated, not only in Great Britain but on the continent of Europe, by the invention of mole plows that can be hauled by a suitable agricultural tractor The cost of the work is substantially less than when performed by steam tackle and is far more expeditious than when performed by horses. The tractor has also rendered it easier for the farmer to undertake deep plowing and subsoiling, which are very important for growing a crop such as sugar beets. Subsoiling had been looked on with disfavour because of the heavy strain imposed upon the teams and, when carried out at all, had been left in great measure to steam tackle. The application of the internal-combustion engine also enabled designers to produce machines of more moderate size and weight than formerly. Another direction in which the internal-combustion engine is likely to prove its usefulness is in rotary tillage.

The internal-combustion engine enables operations to be efficiently performed which were beyond the resources of the ordinary farmer, or which were little more than ideas in the days of steam and horse labour. But this is not its only or perhaps its chief usefulness. It enables operations to be performed far more speedily with an equal labour force and is therefore an ally to the farmer in his struggle against adverse weather conditions. Obviously, if five or six acres can be [illegible] in a day by a tractor where formerly a plow team [illegible] for less than one acre, another factor than the unit cost of the plowing, namely, that of speed or of the time conditions, has entered into the operations. Again, if 20 acres can be reaped in a day as against 10 or 12 acres by two teams of horses, the same factor enters.

**Electricity.**—But a still newer source of power on the farm is electricity. Because of the shortage of coal and oil fuel during World War I, a stimulus was given to the exploitation of water power and the generation of electricity. Although employed at first principally for lighting, electricity, when it is available at low cost relatively to other forms of power, is gradually coming into use for driving stationary machinery on the farm. Beginning after World War I, there was a rapid increase in rural electrification in many countries of Europe and in the United States. The increase was especially noteworthy in the United States, where in 1944 it was estimated more than 40% of the farms had electricity and agricultural engineers predicted an increase to as much as 75% in the first decade after World War II. The principal new uses developed were for heating chicken and pig brooders and for refrigeration.

**Rise of Farm Mechanization in the United States.**—Because of the rapid development of mechanized agriculture in the United States, special attention is devoted to some of the highlights of its history. During the colonial period (1607 to 1783), farming was on a self-sufficing basis; that is, the farmer made his own shelter, he and his family made much of what they wore, and, with the exception of some wheat, tobacco, rice and indigo, the farmer raised but little more than was required for his own family. The ground was spaded or hoed up, or it was plowed with a crude "bull" plow which carried a wooden mouldboard sometimes stripped with iron. If the seedbed was harrowed at all, a peg-tooth harrow was used; this was a wooden frame with wooden spikes for teeth. Small grain was sown broadcast by hand sometimes it was harrowed in or was trodden in by animals. The new crop was cut with a hand sickle, scythe or cradle, threshed with hand flail or by driving animals over it on a treading floor; then the grain was winnowed by casting it against a light wind. Corn was dropped, covered, cultivated and harvested entirely by hand. Wooden wheeled carts were used. Thus, with the exception of a great number of hand tools, crude forms of the plow, harrow and wagon were the only agricultural implements of the colonial period

With only one or two notable exceptions the same conditions held and the same old implements were used throughout the second period (1783–1830) of agricultural history. Early in the 1790s the Whitney cotton gin appeared; this made the removal of the seed from the cotton fibres mechanically possible and was a great boon to the young cotton industry. The influence of the cotton gin was so far-reaching economically, commercially and socially that it is considered one of the high lights in the history of agricultural machinery.

About 1797 Charles Newbold demonstrated his cast-iron plow It was similar to the cast-iron plows which had been demonstrated shortly before in England. Records indicate that farmers feared detrimental effects from so much iron in contact with the soil, and evidently this first American cast plow was never repaired after its mouldboard became broken. Hence wooden plows, some of which carried wrought-iron cutting edges, continued well throughout the period Between 1814 and 1820, however, Jethro Wood, evidently continuing the mediations of Thomas Jefferson on the mathematics and mechanics of the mouldboard, began to give the plow bottom scientific shape for better turning, pulverizing and for lighter draught. To obtain these shapes Wood had to cast his plows, and he introduced the important feature of having various parts of the plow renewable.

At no time has American agriculture undergone such changes as during its third historical period (1830 to 1860). At the beginning of this period the farmer produced first for himself and family; at the close he was raising crops chiefly to sell.

The obstinate scouring qualities of the soils in the Mississippi valley led to the use of steel instead of iron strips to face the mouldboards of plows. In 1833 John Lane built the first steel mouldboard, using crosscut saw blades for the purpose. John Deere starting in 1837, and William Parlin beginning in 1842 were other pioneers in the steel plow business of the middle west. Much credit is due also to James Oliver who, beginning his experiments in 1853, greatly advanced the process of chilling cast plow parts, thus securing greater durability and improving the scouring qualities of this type of plow

Early in the '30s the Manning, the Hussey and McCormick patents brought out the idea of cutting grass and grain by a reciprocating knife passing through fingers or guards. It is this principle upon which modern mowers, binders, headers and combination harvester-threshers still operate.

By 1850 several factories had been established for the manufacture and sale of what were then improved and successful plows, harrows, grain drills, reapers, mowers, threshers, strippers and power sweeps. Of course much work on the farm still had to be done by hand, and much improvement and many new devices were to appear after that date. But by that time the farming public was accepting mechanical devices so rapidly that 1850 is recorded by historians as the close of the period of "hand production" and the beginning of the machine era in American agriculture. The advent of machinery and implements placed farming on a commercial basis on which the farmer raised products to sell rather than simply to sustain himself and family. It is interesting to note that from 1850 to 1860 the number of establishments manufacturing agricultural machinery increased from 1,333 to 2,116.

From 1850 to 1860 patents appeared and there was development work on each of the following: force-feed devices in grain drills, stalk cutters, baling presses, two-row corn planters, disc harrows, feed grinders and "straddle row" cultivators. Improvements continued on all classes of implements, especially on mowers, threshers and reapers. One of the most interesting developments concerned mechanical binding attachments made for and used to some extent on reapers.

The fourth period in the history of American agriculture extends from 1860 to 1887. It was characterized by remarkable expansion, a chief cause of which was the passage of the homestead acts. The disbanding of the armies of the Civil War sent men and mules back to the land, and, machinery being available, many sought the agricultural opportunities of the far west which was about to be opened up by the completion of the transcontinental railroads. The perfection of the twine binder and the introduction of the roller process for flour manufacture also stimulated agricultural expansion.

The drain of the Civil War on farm labour forced farmers to the use of more and more machinery. During the war, mowers came into very general use, and early in the period much was done to perfect horse rakes, which, as an accompaniment to the

mower, could displace more labour in the haying process. This was to be followed soon, in 1872, by the development of hay forks, slings and carriers by which hay could be moved from the wagon to the mow or to the stack by horse power rather than by hand. Thus the production of hay became mechanical save for one step—that of loading. This gap began to be closed in 1874 when the mechanical hay loader appeared; the implement was considerably improved about 1880 and came into use about 1885 Although they had been patented years previously, two-wheeled sulky and gang plows did not appear in good quantities until about 1870.

The first automatic grain binder—that is, the first harvester of the Marsh type to carry an automatic bundle forming, compressing and tying attachment—appeared in 1870, and was known as the Locke machine. At last the tedious process of binding sheaves by hand was doomed, and the importance of this development in the history of agriculture can hardly be overestimated. Attachments using twine as the binding material, and some using wire, followed quickly. About 1878 the famous tying device known as the Appleby knotter appeared. It became the standard tying mechanism of nearly all modern grain, rice and corn binders. Thus the grain binder was the result of 40 years of struggle.

Although combination harvesters and threshers had been thought of as early as 1826, it was not until about 1875 that the combine came into use, and then it appeared in the vast wheat fields of the Pacific coast states. These were large machines, drawn by from 12 to 30 horses, cutting a swath of grain from 16 to 24 feet wide, and threshing, cleaning and sacking the grain in one trip over the field.

In 1875, largely through the activities of the Haworth brothers, automatic checkrowers for planting corn became practical. The dropping mechanism in these machines was operated by regularly spaced buttons or knots on a wire stretched across the field, instead of by an extra man on the planter. Thus one man, and the previous operation of marking off the field were eliminated from the planting process. In 1876 manure spreaders of the wagon type were developed to the practical stage. About the same time ensilage cutters, or silo fillers and disc plows appeared, the latter, however, did not become commercially practicable until about 1890. Although stationary steam engines, and steam engines on trucks which could be hauled from place to place had been used previously, the self-propelled steam traction engine did not appear in agriculture until about 1880. This was the forerunner of the modern tractor. In 1884 three-wheeled sulky and gang plows were developed. About 1885 a combination machine for husking corn and shredding the stalk made its appearance.

The fifth period in American agriculture, 1887 to about 1940, began with the practical exhaustion of those public lands in the United States which could be converted easily and cheaply into quick producing farms. After 1887 agriculture had been settling down to more intensive cultivation accompanied by improvement in farms and the subsequent rise in land values. (The same tendency is in evidence in Canada, though there the corresponding periods are from 10 to 20 years later.) Obviously attempts to intensify and diversify agriculture involved machinery and implements in no small way.

The period opened with many of the most fundamental types of agricultural machinery well established. Minor improvements continued in all classes of implements. Sled corn harvesters, corn binders and side delivery rakes to facilitate loaders came in early in the period. These were great labour savers. Inasmuch as one man with three horses on a two-row cultivator can cultivate 90% more acreage per day than one man with a single-row machine, it was only natural that attention should be given the two-row cultivators which began to appear early in the '90s. About 1890 the Babcock device and system was developed for determining the butterfat content of milk and cream. The Babcock test helps the farmer cull the unprofitable cows from his herd. Cream separators appeared about 1890, and a great labour saver, the milking machine, came into use about 1910.

Among the early attempts to adapt the internal-combustion engine to farm work no efforts stand out more prominently than those of C. W. Hart and C. H. Parr, two young men who developed very satisfactory, stationary, gasoline (petrol) engines as early as 1896. A little later they conceived the idea of mounting a gasoline engine on a truck, and gearing the two together so that the combined unit would propel itself. In 1902 these men built such a machine and proved that the gasoline engine could be used for haulage purposes. A new industry, the great modern tractor industry, was born. Manufacture began almost immediately by several companies, and within nine years a large number of tractors were plowing, harrowing, seeding and threshing in those regions of the United States and Canada where the farms and fields were large. These early tractors were large, heavy and somewhat crude. Being able to develop 30, 40 and sometimes 50 horsepower at the drawbar, they pulled six-, eight-, ten- and twelve-bottom plows, or large combinations of soil preparation and seeding implements.

The tractor had demonstrated its ability to get work done quickly with a minimum of human labour, and, in farming, getting work done when weather, crop or soil is right is a decided advantage. The old heavy tractors, however, required considerable outlay in cash, and they were too unwieldy for practical use except in large fields. About 1910 the power [illegible] d so thoroughly gripped agriculture that suddenly a demand for small tractors developed from farmers on smaller tracts, and many of the old manufacturers, together with a great number of new tractor concerns, began bringing out smaller tractors. This tendency to cut the size, power, weight and price continued until the light tractor of 8–16 and 10–20 horsepower came onto the market about 1916 and brought with it the light, two-wheeled tractor plow which was quite an innovation in plow design. The light tractor and light plow, selling at prices which made their use economical on small farms, introduced power farming onto thousands of farms in both the United States and Canada, farms which could not have enjoyed their advantages had not smaller, cheaper units been made available. Likewise, small sizes of grain threshers, of ensilage cutters and of feed grinders became popular because the presence of the small tractor on the farm enabled the farmer to perform these respective operations himself instead of having to depend upon the custom outfit which previously had passed from farm to farm doing belt work for hire. By 1944 the United States had 2,000,000 farm tractors, mostly of the handy size, and in Great Britain during World War II the number increased from 55,000 to 160,000 by 1943.

Another major development in the current period of agriculture is the mechanical corn picker. Such a machine was talked of in 1851; some were built and successfully operated about 1910, but not until about 1920 did it really start to take its place in the corn belt. Likewise, rotary hoes, for rapid corn cultivation, were in 1928 just beginning to become popular, although they had been on the market for 20 years.

Although the motor truck is not strictly a farm machine it has proved to be one of the most helpful to farmers. In the U.S. it was estimated in 1944 that 1,100,000 were used on American farms, mostly lightweight ones of the pickup sort.

Among the noteworthy developments in farm machines during the 1930s and '40s were improved planters of various kinds, some very special ones such as machines for planting "sheared" sugar-beet seed, specially cut down so as to produce more single plants and reduce the work of thinning; then there were also many new designs of planting plates, particularly those for planting seed and hybrid corn, including the irregular butt and tip kernels (worth saving when the price is high) and those for planting the very small seeds of some vegetables such as turnips, radishes, cabbage, etc. At the same time devices were developed to make feasible aeroplane planting of rice in California.

In this same period many new harvesters appeared such as the corn picker-sheller, the self-propelled combine harvester-thresher, very small combines for many crops and small farmers, and there were many crop varieties developed with the idea of fitting them better to machine harvesting, for instance, bush snap beans that would produce much of the crop at one time so the plants could be pulled and taken to a machine for picking off the beans, thus

saving hand labour.

The development of new planters and cross-blocking machines for sugar beets was noteworthy as a combination of efforts to produce a good yield while at the same time eliminating much heavy labour. There was considerable development of flame weeders, especially in sugar-cane fields. There was a decided tendency toward more surface cultivation in contrast to deep cultivation. This meant greater use of such tools as duckfoot cultivator shovels.

Significant changes came in ways of fighting insects and fungi. One of these was the aerosol method of spreading, which, at least insofar as field crops were concerned, was still experimental in 1944. The method is to use a highly volatile chemical liquefied under pressure in a steel cartridge and containing the insecticide or fungicide. Opening a valve causes automatic spreading. Such equipment was widely used by military forces during World War II for control of flies and mosquitoes. In addition new insecticides, fungicides and materials for control of nematodes appeared. Machines were made for applying picric acid and "DD," a petroleum by-product, to the soil to kill nematodes.

**Manufacturing.**—As the farmer found increasing need for more complicated machines and more different kinds of tools and machines with greater variety in agriculture, the manufacture of farm machinery became a great industry, especially in western Europe, Great Britain, the United States, and, after 1920, in Russia. In most other parts of the world the manufacture of farm machines is of only minor and local importance, except perhaps in Canada, South Africa, Australia and New Zealand where considerable numbers of machines are made. The United States is the largest user and the largest producer of farm machinery.

In all the progressive agricultural countries the value of farm implements on farms increased rapidly after 1850 and even more rapidly after 1900, with the widespread adoption of mechanical power for both field and stationary work. As a result of the demands of war, values of machinery on farms receded, but at the same time more thorough use has been made of the implements available. During World War II the practice of pooling farm machines became common in many countries and old machines were brought back into use through repair work and replacement of parts.

One factor of great significance is the rapid increase in durability of many machines, the result of improved materials such as alloy steel, better design and more effective lubrication. These factors no doubt accounted in great degree for the extra wear obtained from farm machinery in wartime.

Credit for the improvements in farm machines during the modern period is not only due to the scores of inventors such as Jethro Tull, Eli Whitney, Obed Hussey, Cyrus Hall McCormick and John Deere, but also to the improvers of steel, the manufacturers and their laboratories, and government and private agricultural research institutions. Through such organizations as, in the United States the American Society of Agricultural Engineers there has been close co-operation that has speeded developments.

Improved steels really made it practicable to have farm machines move faster in the field, such as mowers, binders, combines and other harvesting machines. These new materials have made it possible for manufacturers to reduce the weight of many implements and to produce more durable parts such as mouldboards of plows and the shovels of cultivators.

Changes in design, of course, have been frequent. Some of the more outstanding have been: changes in plows which provide more space between the mouldboard and the beam, thus reducing the tendency to clog with trash; plow jointers that tend to avoid obstructions and return to the original line of travel, thus reducing draught; enclosed gears that require infrequent lubrication and wear long because they are kept clean; forced lubrication on some of the more complex machines; planting plates and other seed-spacing devices that greatly improve accuracy of plant placement and cut down later labour in tending the crop. These are but a few of many examples that may be cited.

In 1933 the American Society of Agricultural Engineers published a report of a survey made by a group of eminent agricultural engineers on "changes in the quality values of farm machines over a 20-year period (1910–14 to 1932)." These changes in quality values, the result of various factors, were expressed simply in figures by letting 100 represent the quality value at the beginning of the period and then arriving at a figure for the increase in value resulting from various changes. Twenty-five machines were studied in this way.

The index of quality value of the grain binder (horse-drawn), for example, rose from 100 in 1910–14 to 170 in 1932. This estimate of increase in quality value in this one machine was based on 65 engineering developments which were listed in the report A few of the developments mentioned were: binder driving shaft changed from 10 to 30–40 carbon steel, knotter frame strengthened, heavier teeth in main gear and pinion, and knotter hook made of steel rather than malleable iron.

Following is a list of the other 24 machines and the quality index figure for comparison with the base of 100 representing the quality value of 20 years before: cultivator (single-row riding, pivot wheel), 165; farm engine (gasoline), 200; disk harrow (horse-drawn), 190; peg-tooth harrow, 130; spring-tooth harrow, 140; hay loader, 155; mower (horse-drawn), 170; corn picker, 210; corn planter, 155; tractor plow, 190; gang plow (two-furrow, horse-drawn), 150; walking plow (one-horse), 140; walking plow (two-horse), 140; sulky rake, 135; side-delivery rake and tedder, 140; cream separator, 145; corn sheller (power), 190; corn sheller (two-hole hand or power), 190; sheller (one-hole hand), 170; manure spreader, 180; grain thresher (steel), 195; feed grinder, 175; ensilage cutter (or silo filler), 215; and spraying machine (two-nozzle), 175.

Many improvements have been brought about in farm machines after the making of the survey on quality values. Experience has shown that technical improvements in all sorts of mechanized equipment are sooner or later reflected in better farm implements. Because of the high pressure exerted for improvement of mechanical equipment of many kinds during war there is usually a period of varied and rapid change following hostilities.

**AGRICULTURAL PRICES.** Prices of agricultural products were of little importance when agriculture was virtually self-sufficing. They are of paramount importance to the typical commercial farmer of today, who sells most of what he produces and buys most of the things he needs for family living as well as many of the things he uses in production. The relation which prices of agricultural products bear to the farmer's living expenses and his expenses of production are of primary importance in determining not only the welfare of agriculture but also what farmers will produce and how much.

From the historical standpoint, special interest in agricultural prices centres on (1) the development of markets and methods of price determination, and (2) the periods of agricultural price depression and prosperity which have resulted from changes in agricultural and other prices.

**Development of British Markets.**—In the early stages of English agriculture the mass of producers were content to satisfy their own wants and were practically indifferent to outside trade. Later, however, the need arose for some machinery for bringing buyers and sellers into touch, and this was met by the institution of fairs and markets held at fixed places and periods. These in the first instance no doubt arose spontaneously, but it speedily became apparent that the holding of a fair or market in a town could be made a source of profit to the burgesses, or if there were no sufficiently [illegible] community, to the lord of the manor. Thus arose a system of tolls on goods exposed for sale in the market. The crown, exercising its authority as overlord, saw at once an opportunity of revenue and claimed and exercised the right to forbid the holding of a fair or market except under royal charter, which was granted on terms. Tolls and regulations of the market would tend to raise the price level, but the effect could only have been slight.

A more serious effect on agricultural prices was caused by legislation against the practices of badgering, forestalling, engrossing and regrating, which was passed in the early part of the 16th century and did not disappear from the statute book until late in the 18th century. The purpose of this legislation in restraint of trade was to protect the consumer from trade practices which were presumed to raise artificially the price of food. A "badger" was a dealer in food who bought in one place and sold in another. He was licensed for a year and was under recognizances against forestalling, engrossing and regrating. Forestalling was purchasing food on the way to market with intent to sell it at a higher price; engrossing was attempting to control—in modern phraseology to "corner"—the market by buying up all the food for the purpose of exacting higher prices; regrating was the resale of food previously bought in the same market.

The state for many centuries intervened directly in the regulation of the price of wheat and bread. From the Norman conquest to the reign of Henry VI the exportation of wheat was prohibited, although in earlier times it had been common. Importation was unchecked, although there is no record of it until the 14th century. In 1436 an act was passed authorizing the exportation of wheat whenever the price did not exceed 6s. 8d. per quarter and in 1463 the exportation of corn was forbidden until the price exceeded that at which exportation ceased. Thereafter a succession of enactments were passed some giving a bounty on exports, others imposing a duty on imports, or adopting both methods under limitations of prices. In 1774 an act was passed permitting imports at a nominal duty of 6d. per quarter when the price reached 48s. and forbidding exports unless the price was below 44s. when a bounty of 5s. per quarter was given on exports in British ships.

Up to this time legislation had for its main object the interests of consumers while attempting also to have regard to the interests of producers, and also to encourage shipping. In 1791 the first of a series of acts was passed which, with increasing stringency, aimed mainly at protecting the interests of home wheatgrowers, which continued until the repeal of the Corn Laws in 1846.

In the 13th century the Assize of Bread was established, by which the duty was imposed on justices of the peace of adjusting the weight, quality and price of bread to the current prices of wheat. The system was modified in detail from time to time, but continued in force until 1822 in London and until 1836 in the provinces.

In later times the establishment of great markets in the large centres of population did much to determine prices on the basis of general and not of local supplies. Many of the markets developed from local to national importance by reason largely of their position in relation to means of communication. Covent Garden is a notable instance. It was originally a place where growers of fruit and vegetables in the vicinity of London could dispose of their produce direct to retailers and consumers. The convergence in the metropolis of the main lines of railway made it a national distributing centre, serving, through various channels, all parts of Great Britain, and "Covent Garden prices" became the standard of values throughout the country.

The organization of commercial price-making on a national basis had, however, scarcely been completed when a new factor was interposed which speedily changed the basis on which price levels of some of the principal foodstuffs rested. Imported wheat, meat, cheese, butter and other kinds of agricultural produce were sent to the British markets in ever-increasing quantities. As they increased in bulk and improved in quality their influence became so great that prices in the wholesale markets were determined on an international rather than on a national basis.

The most prominent instance of this modern development is to be found in the wheat trade, where imported grain, forming as it does about four-fifths of the whole supply, dominates British prices and determines the value, at any given time, of British wheat

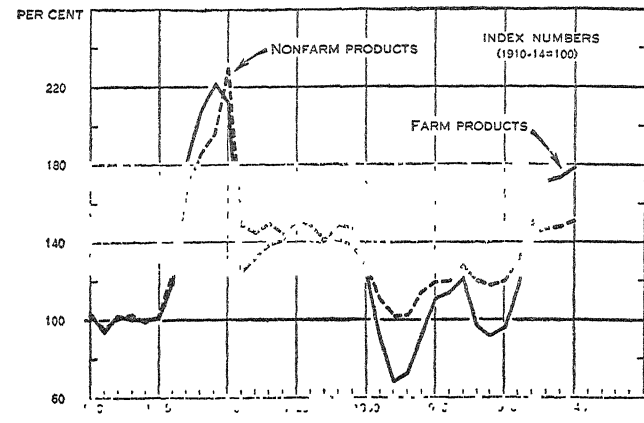
Price-making arrangements in the wheat trade are highly organized. World's prices are practically settled at four great markets, viz., Chicago, Winnipeg, Liverpool and London, and so well adjusted and sensitive is the mechanism that fluctuations in one are immediately reflected in the others.

**Prices in America.**—Prices have been important to American agriculture ever since early colonial days. Although the agriculture of the frontier regions was always largely self-sufficient, much of the total output was for sale either in the domestic or the export market. As the frontier was pushed westward into the fertile valley of the Mississippi. an ever-growing volume of agricultural products was shipped either down the rivers or eastward to the older settlements to be exchanged for all kinds of manufactured products. This rapid growth of agricultural production in America during the 18th century also had a profound effect upon prices throughout the commercial world. Cheap food and cotton from America was basic to both the growth of manufactures in Britain and to the decline in British agriculture.

Throughout most of the history of the United States, the determination of prices of agricultural products has been left to private competitive enterprise in the market places. Tariffs and other government regulations have had their influences, but the actual process of price determination has been left almost entirely to the bargaining of private enterprisers. The most notable exception was during World War II, when price ceilings were

established for most farm products as well as for other products Nevertheless, prior to the war there had been a growing government participation in the process of agricultural price determination. The Federal Farm Board, through its loan and purchase operations from 1929 to 1933, had an important influence. The Commodity Credit corporation, operating on a larger scale, was a much more important market factor from 1933 on. These loan and purchase operations, together with the influence of the Agricultural Adjustment administration and the soil conservation service upon agricultural production, indicate that the United States has been moving toward a degree of control over agricultural prices comparable to that attained by some European countries a decade or more earlier.

**The Course of Agricultural Prices.**—Agricultural prices in the United States from the beginning of the 19th century have been influenced by four periods of inflation. The first was due to the War of 1812, the second to the Civil War, the third to World War I, and the fourth to World War II. After each inflationary peak there has been first a sharp decline and then a rather long period in which the general trend of prices has been more slowly downward. In a general way the prices of agricultural and nonagricultural products moved together. However, over the entire period agricultural prices have risen relative to the others—owing to the less rapid improvement in the arts of agricultural production.



Price changes in England have been somewhat similar to those in the United States, but in England there was no price inflation corresponding to that during and immediately after the Civil War in the United States. Instead, there was a period of gradually rising prices and of agricultural prosperity from about 1850 to 1872. This was in contrast to the long period of falling prices and chronic agricultural depression which had prevailed for about thirty years following the Napoleonic Wars.

From about 1873 to 1895 agricultural prices declined gradually not only in the United States and in England, but also in other countries whose currencies were maintained at a constant level in relation to gold. In England rents fell and marginal land went out of cultivation. In the 1890s, a British Royal Commission stated, "We have no hesitation in expressing our entire concurrence in the opinion that the crisis in agriculture is due primarily to the fall in prices."

Conditions in the United States during the latter part of the 19th century differed greatly from those in England. The area under cultivation was constantly expanding. In the newly settled areas, rents and land values tended to rise at times because of improvements in transportation and in methods of agricultural production, especially the greater use of machinery. For the older settled regions of the United States, however, conditions bore much more resemblance to those in England. Even in the West, where many of the pioneers pushed on from one new frontier to another, exploiting the virgin soil resources as they went, agriculture was not very prosperous because of the declining price level.

The course of wholesale prices of farm products and nonagricultural products in the United States is shown by the accompanying chart from 1910 through 1945. There have been few times from 1920 when the prices of farm products have been as high relative to nonagricultural products as they were in the base period, 1910–14. If the comparison is made between prices received by farmers at their local markets and the prices paid for the goods they buy at those markets it is still more unfavourable to agriculture. Increases in freight rates and other marketing costs widened the spread between local market and central market prices and resulted in an increase of retail prices relative to wholesale prices. As a consequence, there was no time from 1921 to 1941 when the index of prices received by farmers was as high relative to the 1910–14 base as was the index of prices paid, interest and taxes.

**Parity Prices.**—The disparity between prices received and prices paid by farmers was generally viewed by agricultural leaders in the United States as the primary cause of agricultural distress from 1920. Parity, or the level at which prices of farm

COURTESY, U S DEPT. OF AGRICULTURE

WHOLESALE PRICES OF FARM PRODUCTS AND OF ALL COMMODITIES OTHER THAN FARM, UNITED STATES, 1910-45

products would be as high relative to the prices of things farmers purchased as they were in 1910–14, was widely accepted as the proper goal of agricultural programs. At first the term parity was applied only to each individual farm product. The parity principle as applied to individual commodities became a part of the Agricultural Adjustment Act of 1933 and has since appeared regularly in laws relating to agricultural aid and prices of farm products. The desirability of maintaining prices of individual products at the legal parity has been questioned by economists because the formula does not make allowance for changes in costs of production, in size of crops, or in other things which affect the normal prices of commodities.

**Differences Between Countries.**—In most countries of the world prices of agricultural products rose during World War I. The extent of the rise and the timing of any subsequent decline depended upon the extent of the inflation and when that inflation reached its peak. The course of agricultural prices in England was fairly similar to that in the United States, but the rise was greater and the decline of the early 1920s was less precipitous and longer continued. In Germany, agricultural prices shot upward under the influence of a postwar hyper-inflation until the end of 1923, when a new currency was established having the same gold equivalent as the old mark. In France, after a temporary decline in 1921 and 1922, prices continued to rise until 1926 when the franc was stabilized at about one-fifth of its former gold value.

Differences in the movement of agricultural prices in the various countries during and after World War I were primarily dependent upon monetary—including credit and foreign exchange—conditions which affected the value of the particular country's currency. Most countries, however, experienced one or two periods of severe declines in agricultural prices at some time between 1919 and 1932. In many countries, however, agriculture did not suffer during the 1920s from prices which were low relative to those of industrial products.

As a result of World War II there were again rapid increases in the prices of agricultural products in most countries of the world. Government price controls were soon resorted to in almost all countries. The degree of effectiveness of the controls varied greatly, as did also the difficulty of the problem of holding inflation in check. The potential inflation as measured by the increase in bank credit and money supply was generally much greater than during World War I, yet through 1945 price increases were less than during the 6½ years following the outbreak of the previous war.

**Factors Affecting Prices.**—Since about 1920 a great deal of attention has been devoted by economists to statistical and other studies of the factors affecting prices of agricultural products. These include analysis of the prices of individual products, of the relation of agricultural prices as a group to prices of other commodities, and studies of the general price level. Studies of individual products, and even of agricultural products as a group, have been quite successful in arriving at quantitative measurements of the influence of various factors upon prices. Studies

of the general price level have been less successful, not because of inability to measure the numerical relationships involved, but because clear evidence is often lacking as to the causal connections.

It is apparent, nevertheless, that whatever are the monetary and other influences responsible for changes in the general level of prices, these same factors have been important causes of the variations in prices of all agricultural products since 1914. In addition, prices of agricultural products have been largely influenced by changes of industrial production and employment—that is, by changes in the general level of "real" demand. Finally, prices of the individual products have been greatly influenced by various factors which relate specifically to the commodity itself, such as supplies of the commodity and of competing commodities.

Much of both year-to-year and seasonal price fluctuations of agricultural products is occasioned by variations in the weather, but there are also important fluctuations which are the consequence of shifts in agricultural production in response to price changes themselves. Cyclical variations in hog prices are an important example of the latter. (E. J. Wg.; R. H R.)

**AGRICULTURAL RESEARCH**, if broadly defined, may be said to have begun when primitive man commenced to observe his experiences with crops and livestock and to interpret his findings with resultant improvements. In modern times it is limited to the manipulation of things, concepts or symbols, with a view to formulating generalizations which verify, correct or extend mankind's knowledge of all processes concerned with agriculture. Such knowledge may facilitate the construction of a scientific explanation or promote the practice of actual farming. Thus defined, agricultural research encompasses all work in the natural and social science fields that are concerned with or affect agriculture.

In Graeco-Roman times the art of agriculture reached a comparatively high state of efficiency, but this development was based upon centuries of observation and experience rather than research. Scarcely any progress was made in deriving true scientific explanations of the chemical, physical, and biological processes involved in agriculture. The Greek love of speculation gave rise to numerous physical theories, but the validity of these systems could only be established by experimentation. For this mankind had to wait for more than 1,000 years after the disintegration of the Roman empire until Theophrastus Paracelsus (1493–1541) attacked speculative philosophy as the source of knowledge and bid his followers put their faith in experience.

The progress of agricultural research from mediaeval times to the controlled laboratory and field [illegible] of the 19th century was tortuously slow. Its history is [illegible] with that of the modern beginnings of the various sciences and is replete with famous names. Prior to the onslaught of modern industrialization and its accompanying urbanization there was no reason for the segregation of the agricultural part of these sciences or for specialization on distinctly agricultural problems except as determined by the personal interests and experiences of experimenters. For example, the chief contributions of Bernard Palissy (1510–1589), the French craftsman, were in the field of ceramics, and yet his investigation of the nature of soils and fertilizers justifies his being called the founder of agricultural chemistry.

By the beginning of the 19th century the sciences had reached stages of development where further progress seemed dependent on field experiments. Antoine Laurent Lavoisier (1743–1794), who established the foundation of the structure of modern chemistry, conducted numerous experiments on his farm at Blois, France, and prepared reports on his findings with a view to improving agriculture and relieving the poverty of his peasant neighbours. In 1784, Albrecht Thaer (1752–1828), began to turn his attention to agricultural research on an estate near Celle, Germany. In 1802 he converted this estate into an agricultural institute where he lectured on farming. Heinrich Einhof (d. 1808) assisted by teaching the relations of chemistry, physics and mineralogy to agriculture, and many future scientists received their initial training at this institute. In 1804, Thaer was called by King Friedrich Wilhelm III of Prussia to head a new state agricultural institute at Möglin. Another pioneer in the use of field experiments was S. F. Hermbstädt (1760–1833), a professor at the University of Berlin, who, from 1815 until [illegible] investigated the chemical composition of cereals and the influence of fertilizers on the production of the proximate constituents of plants.

The modern aspect of agricultural research began with the field experiments of Jean Baptiste (Joseph Dieudonné) Boussingault (1802–1887). Earlier scientists had developed much knowledge concerning the elementary composition of agricultural products, but no one had sought to [illegible] balance of chemical elements in the growing of crops or in the feeding of animals. It remained for Boussingault to seek scientific facts in the fields and stables. Following an adventurous career as a mining engineer in South America, he settled on a farm at Bechelbronn in Alsace where he conducted a carefully planned series of field experiments from 1834 until his land became German territory in 1871. By quantitative methods he investigated the changes in the elementary composition of seeds during germination; the assimilation of atmospheric nitrogen by plants; the rotation of crops; the use of fertilizers; the care of barnyard manure; the nutritive value of forage crops; the feeding of livestock; the influence of feed on the yield and composition of milk; and many other practical agricultural problems. These experiments, co-ordinated with laboratory controls, pioneered in the problems of feeding crops and provided the basis of all modern field work. The facts gathered by this and other methods were reduced to order by Justus von Liebig (1803–1873) in 1840 and later in his brilliant generalizations on plant nutrition and crop production.

In Britain J. B. Lawes (1814–1900) began to experiment with artificial fertilizers at his Rothamsted estate in 1836. Formally organized by Lawes and Sir Joseph Henry Gilbert (1817–1901) in 1843, these experiments are still carried on, and thus Rothamsted ranks as the oldest agricultural station in continuous operation. The effects of their artificial fertilizers on the soils of Britain were so striking that similar experiments were soon made in most countries with mature agriculture. Although the results were not always as clear and definite as in Great Britain, the experiments opened the way to new knowledge of soils, crops and livestock In the United States where water supply was often a limiting factor in crop production, these experiments led to important developments in soil physics; in France, to the important contributions of Georges Ville (1824–1897) on the use of fertilizers; and in Russia, to far-reaching studies of soil morphology. Animal nutrition was also studied by Lawes and Gilbert at Rothamsted, but considerably developed in Germany.

In due course [illegible] and experiment stations were founded as research centres in almost every civilized country. Eventually most countries also created departments of agriculture in their governments which conducted extensive research as well as supervisory and regulatory work. The needs of World War I compelled rapid integration of special studies and emphasized the desirability, if not necessity, of a higher degree of co-operation and co-ordination of research projects, not only within countries and empires, but also internationally. Although impoverished by the war, the European countries extended their organizations for agricultural research in the 1920s and 1930s, and eventually most countries had experiment stations owned and financed by the state; frequently others were financed by private grants, agricultural organizations, or trusts. World War II brought further and greater recognition of the contributions of agricultural research in its many fields to the welfare of mankind.

In Britain parliament provided the development fund in 1909 at the instance of David Lloyd George and assigned a capital sum of £2,000,000 for rural development, including agricultural research and education. It was decided to make grants to existing institutions, holding each responsible for certain fields of agricultural research, rather than to create new stations to cover all fields. The main subjects and the institutions to which they were assigned are: Soils, plant nutrition, and plant pathology at Rothamsted Experimental station; animal nutrition at the Rowett Research Institute, Aberdeen; plant physiology, at the Imperial College of Science and Technology, London; plant breeding at

Cambridge university, the University College in Aberystwyth and the Scottish Plant Breeding station in Edinburgh; fruit research at Long Ashton, Bristol and at East Malling, Kent; the glasshouse industry at Cheshunt, Herts ; animal breeding at Edinburgh university; dairying at Reading university, the Royal Veterinary college in London, and the Scottish Animal Diseases Research association; animal parasitology at the London School of Hygiene and Tropical Medicine; and agricultural economics and engineering at Oxford university. The development fund was augmented in 1921, and additional aid was provided through the Empire Marketing board established in 1926. The agricultural societies continued also to make grants.

In Canada one single result of agricultural research, namely, Marquis wheat, has long since repaid all expenditures for experimentation in the commonwealth. A school of agriculture, eventually affiliated with Laval university, was established at Ste. Anne de la Pocatière, Que., in 1859; the Ontario Agricultural college, founded at Guelph, Ont., in 1873, carried on experimental work; and Prince Edward Island had a government stock farm at an early date. It remained, however, for the Dominion Experimental Farms system, established in 1886 after an extended investigation of agricultural conditions by a select committee of the Canadian house of commons, to provide most of the research needed by a vast country with widely varying agricultural conditions and problems. Under the first director, William Saunders (1836–1914), the Central Experimental farm was located at Ottawa and the original branch stations at Nappan, N.S., Brandon, Man., Indian Head, Sask. and Agassiz, B.C. Eventually 29 other stations and about 200 illustration stations were added to the system.

In Australia, the wheat-breeding work of William J. Farrer (1845–1906) at Lambreg, New South Wales, and of his continuators at other stations, contributed much to arable farming. Special attention has also been given to pastoral problems. The Waite Agricultural Research institute, established at Adelaide under A. E. V. Richardson in 1924, began a wide range of planned experimentation, and the Council for Scientific and Industrial Research, created by parliament in 1925, provided federal funds and co-ordination for all stations within the commonwealth. In New Zealand, the privately-endowed Cawthron institute was established in 1915, to supplement the work of the state experimental farms and the colleges. In India, the central station, started at Pusa in 1903 with a gift from Henry Phipps, an American, and removed to New Delhi after an earthquake in 1934, was supplemented by state and college stations.

After World War I notable progress was made in other tropical regions. The Imperial College of Tropical Agriculture was opened in 1922, at Trinidad, for training and research in tropical agriculture. The research institute originally founded by the Germans at Amani, in Tanganyika, was reopened and expanded. The veterinary research station at Onderstepoort, South Africa, early won world recognition as the leading centre in its field. The stations at Gezira and Medani in the Anglo-Egyptian Sudan concentrated on cotton and crops used in rotation with it. The growers also organized and financed experimental work; the Rubber Research Institute of Malaya and Tea Research Institute of Ceylon are examples.

The researches of the separate parts of the British empire were conducted independently of the rest until 1927, when an imperial agricultural research conference recommended that the governments of the commonwealths establish on a co-operative basis bureaus to collect, collate and disseminate information on research in selected branches of agricultural science and generally to assist research workers in the empire with data relevant to their subjects. These bureaus are financed from a common fund supplied by the governments in agreed proportions and governed by an executive council with equal members. The bureaus are located in Great Britain at research centres specializing in the respective sciences as follows: Soil science at Rothamsted, Cambridge; animal health at the Veterinary Laboratory, Weybridge; animal nutrition at the Rowett Research Institute, Aberdeen; plant breeding and genetics at the School of Agriculture, Cambridge; pastures and forage crops at Aberystwyth; horticulture and plantation crops at East Malling, Kent; animal breeding and genetics at Edinburgh; and agricultural parasitology at St. Albans. In 1933, the council also assumed financial and administrative responsibility for the already established Imperial Institute of Entomology in London and the Imperial Mycological Institute at Kew. In 1936, a forestry bureau was located at Oxford and one for dairy science at Reading.

In Denmark, the intensive agricultural system which gained the admiration of the world owes much to agricultural research. After their military defeat by Germany in 1864, the Danes sought, as one of their distinguished statesmen said, "to gain within their borders what they had lost without." For many years the Royal Danish Agricultural society contributed to the advancement of agricultural science by appropriations and continued to serve as an important agency to this end after the organization of a department of agriculture in 1896. The dairy investigations, notably the feeding experiments of N. J. Fjord, at the Royal Agricultural college, Copenhagen, were started in 1872. Its laboratories also conducted feeding experiments with pigs, investigations of animal diseases and testing apparatus used in dairying. Although this institution remained the main centre of research, five other stations and a few substations were established for work on soils, plant pathology, horticultural crops and plant breeding. The Danish Heath Society has aided in the reclamation and forestation of new lands. Economic research on co-operatives and marketing also contributed to the advancement of the country's agriculture

In France, a large number of research centres continued the practical example of Boussingault. The agricultural college at Grignon, founded in 1827, was long concerned with agronomical problems. The experiments of Ville, from 1848 to 1863, were made at Vincennes, near Paris. The Station Agronomique de l'Est, founded by Louis Grandeau at Nancy in 1868, emphasized soil investigations. The station at Montpellier studied the vine and its diseases and pests. The Institut Pasteur, although not an agricultural agency, conducted research in plant physiology and microbiology of great importance to agriculture. Soil bacteriology (*q.v.*) began in France as the result of investigations by J. J. Schlosing (1824–1919) and Achille Müntz (1846–1917); other fields were opened up by M. P. E. Berthelot (1827–1907). The striking advances made by S. N. Vinogradsky (1856–1946), who introduced new concepts and more precise methods, made the subject a science. Although the agricultural stations and laboratories were long under the general direction of the ministry of agriculture, they were reorganized into a more comprehensive and centralized system under the institute of agricultural research in 1921 as an office of the ministry of agriculture.

In Germany, an agricultural college was founded at Hohenheim in 1817, but the country had no permanent experiment centre until 1851, when the Economic Society of Leipzig started the station at Möchern in Saxony under Emil Wolff. Similar stations were soon opened, but the most rapid expansion came after the federation of the German States in 1871. Most of the stations were attached to universities and under close government control; they also had certain responsibilities in the regulation of fertilizers, feeds and seeds. In 1888, an association of experiment stations was formed to secure uniformity in methods of investigation and inspection of articles. By the 20th century, the German stations had increased in number and size and had won world-wide recognition. Certain of them contributed to the enormous strides made in the output of synthetic nitrogenous compounds. Among the larger state institutions were those at Halle for animal nutrition, agricultural chemistry and microbiology; at Bonn-Popplesdorf, Königsberg and Landsberg, for soils, plant nutrition, animal husbandry and plant physiology; at Bremen and Landsberg for moor culture; at Breslau, Hohenheim and Göttingen for agricultural chemistry and bacteriology; and at Berlin and Leipzig (Möchern) for many fields of agricultural science. In addition, the nitrogen and potash syndicates and the superphosphate manufacturers maintained private research laboratories.

The Netherlands has several experiment stations which have specialized on the country's particular problems. The station at Wageningen, begun in 1877, is the largest and is especially notable for the work of H. M. Quanjer in plant pathology and D. J. Hissink in soils. The Netherlands has also won commendation for the admirable research work carried out at Buitenzorg in Java and elsewhere in the Netherlands Indies where scientists pioneered in the field of hill culture.

Russia's best-known contributions to agricultural research are in the fields of soil science and plant breeding. The soils work was begun about 1870, under the leadership of V. V. Dokuchaiev (1846–1903), followed by N. M. Sibirtsev (1860–1900) and K. D. Glinka (1867–1927) and others. In contrast with the scientists of western Europe, who analyzed specimens of soils in laboratories, the Russians studied soils in the fields and then supplemented their findings with laboratory data. They concluded that the character of the soil is largely dependent upon its geographical position and climatic environment, and on this basis developed a system of soil classification. Although not widely known outside of Russia until well into the 20th century, the Russian ideas greatly stimulated research in this field. In the work on plant breeding directed by N. I. Vavilov, emphasis was given to thorough exploration of all parts of the world for varieties and breeding material of value and to extensive programs at numerous locations for studying introduced materials in detail and for large-scale hybridization and selection work. Agricultural research in Russia was completely reorganized after the revolution of 1917. The soviet union was reported in 1938 to have had over 14,000 scientists working at 90 agricultural research institutes, 367 experimental stations and 507 experimental farms with numerous branches

The history of the British colonies that became the United States is replete with instances of agricultural experimentation As in all new countries the colonists were obliged to determine by experimental plantings the crops that thrived in the respective localities, and the desirability of encouraging such experimentation through aid from the imperial and local governments was early recognized. A number of distinguished leaders, including John Winthrop, Jr. (1606–1676), William Penn (1644–1718) and Jared Eliot (1685–1763) conducted agricultural experiments. John (1699–1777) and William Bartram (1739–1823) and Humphry Marshall (1722–1801) maintained botanical gardens near Philadelphia, Pa., and a public experimental garden was established at Savannah, Ga., in 1733.

About 1760 George Washington began to study agricultural problems systematically and to make experiments to ascertain the best methods for his Mount Vernon estate and vicinity. Thomas Jefferson gave special attention to natural phenomena in relation to plant growth, introduced plants useful to American agriculture, and made Monticello a veritable experimental farm. For about 30 years, John Beale Bordley (1727–1804) conducted experiments on Wye Island near Maryland's eastern shore, and John A. Binns (1761–1813) devoted two decades to experiments with gypsum in Loudoun county, Va. Beginning in 1785, the efforts of these men and others were facilitated by agricultural societies (*q.v.*), formed for the promotion of agriculture. Among the individuals who made outstanding contributions was Edmund Ruffin (1794–1865), whose essay on calcareous manures has been described as the most thorough work on a special agricultural subject ever published in English. The numerous geological and agricultural surveys during 1820–1857 laid a considerable foundation for the more intensive work of the experiment stations with soils and fertilizers in their relations to plant growth.

Except for special projects, the first federal fund specifically authorized for agricultural purposes was the $1,000 voted the patent office in 1839 for collecting agricultural statistics, conducting agricultural investigations and distributing seeds. With this and later appropriations, an agricultural division in the patent office served as a federal clearinghouse for information on agricultural improvements during the 1840s and 1850s. After long agitation the federal department of agriculture which ultimately became the most extensive agricultural research agency in the world was created by congress and approved by President Lincoln on May 15, 1862. On July 2 of the same year, the bill providing for the establishment of a college of agriculture and mechanical arts in each of the states was signed Beginning in the 1840s steps were taken to establish institutions of research under private and then state auspices, but it remained for the Hatch Act of 1887, augmented by the Adams Act of 1906 and the Purnell Act of 1925, to provide the federal aid that facilitated the development of the national system of experiment stations associated with the agricultural colleges in all the states and territories. To direct the relations between the federal department and the stations, the office of experiment stations was established in 1888. Its publication, the *Experiment Station Record*, has provided abstracts of the reports on scientific research in the U S and foreign countries from 1889.

By the end of the 19th century, discerning leaders throughout the world were becoming increasingly aware of economic and social problems relating to agriculture and farm living The agricultural colleges and the federal department had begun work in this field, and the findings of the Country Life commission appointed by President Theodore Roosevelt served to focus attention on the need of both study and action. In 1913, the federal department was authorized to study the marketing and distribution of farm products. The needs of agriculture during World War I and economic repercussions afterward resulted ultimately in the department's bureau of agricultural economics becoming one of the greatest agencies of research in the social sciences.

Although the stations tended to specialize on the agricultural problems of the states where they were located, leaving to the federal department the investigation of general scientific principles and subjects beyond local means, there was a growing recognition of the need of co-operative action on problems common to several states after World War I. In 1935, the Bankhead-Jones act made special provision for the federal department to undertake scientific, technical and economic research into the laws and principles underlying basic problems of agriculture in its broadest aspects. In the 1920s more emphasis was given to discovery and perfection of new consuming outlets for farm products by the federal department and the stations. Improvements in the sugar industry, the production of casein and the revival of the naval stores industry in the south may be cited as examples. In 1933, a federal laboratory was established at Ames, Ia., to study the industrial uses of agricultural residues like straw, cornstalks, corncobs and hulls. Later a laboratory at Urbana, Ill., began to investigate the possible wider uses of soybeans. In 1938, congress authorized the federal department to extend this type of research upon a comprehensive scale by providing for regional laboratories which were located at New Orleans, San Francisco Peoria, Ill., and Upper Darby, Pa. In 1910, the federal government began to develop what became a national agricultural research centre near Beltsville, Md. By 1945, much of the laboratory and field work of the scientific bureaus of the department of agriculture had been transferred there, and the centre comprised 13,900 ac., 36 laboratory buildings, 31 greenhouses, 100 barns and storage buildings and 500 other buildings.

The interchange of scientific data between the countries of the western hemisphere began in the 1840s, and the need was long felt for inter-American action to carry out research projects which require methodical study and joint action by both the governments and scientists. The first Inter-American Agricultural conference, held in Washington in 1930, recommended the establishment of a Pan-American experiment station to serve this end, and after long negotiation and planning the Inter-American Institute of Agricultural Sciences was inaugurated at Turrialba, Costa Rica, in 1944. Its work was planned to fall in four broad departments: animal husbandry, plant industry and soils, agricultural engineering and economics and rural life.

**AGRICULTURAL REVOLUTION, THE,** a term indicating that period in history which witnessed the transition of English methods of farming from mediaeval to modern conditions. During the 18th century increasing knowledge and new inventions revolutionized both agriculture and stockbreeding. At the same time the rapid growth of enclosures vastly improved the conditions under which farming was carried on. But it increased the resources of the great landowner to the extinction of the yeoman farmer, and thus an essentially progressive movement in agriculture brought much misery in its train. The expenses incurred by the enclosure movement, the subsequent rise in the value of land, reductions in agricultural establishments, the protective system of the corn laws, and the supplementing of wages from the rates (Speenhamland system [*q.v.*] 1795) raised prices, lowered wages and depressed a large section of the agricultural population to the level of paupers. (*Cf.* INDUSTRIAL REVOLUTION.) *See* also AGRICULTURE: A GENERAL SURVEY; COMMONS; CORN LAWS.

**AGRICULTURAL SOCIETIES AND SHOWS.** In agricultural history there is scarcely a parallel to the enthusiasm that spread through Great Britain during the last quarter of the 18th century. Even George III contributed to Arthur Young's *Annals of Agriculture* and became known as "Farmer George." The politicians, including Fox and Burke, the great landowners, such as the Duke of Bedford and Coke of Norfolk, shared in the zeal and were excited by farming topics and busy with farming experiments. One of the results was the organization of associations for the promotion of agriculture in many parts of the country. Among the earliest and most important were the Bath and West of England society (1777), the Highland society (1784) and the Smithfield club (1798). Another result was the founding of the board of agriculture by Pitt in 1793 with Sir John Sinclair as president and Young as secretary.

A chief activity of many of these societies was the holding of an annual agricultural show. As a rural institution combining exhibit and amusement features it is now found in practically all countries of the western world. In Europe and Australia it is known as an agricultural show, while in the United States and Canada it is usually called a fair. Possibly the earliest local agricultural show was that of the Lancashire society in 1761. The first national show was held by the board of agriculture in 1821.

**The Royal Agricultural Society** was founded in 1838 and received its charter in 1840. Its first show was held at Oxford in 1839 under the presidency of Lord Spencer. The classes for cattle, sheep, horses and pigs were limited, but the names of many famous breeders appeared in the award sheet. Nineteen manufacturers were represented in the implement exhibit. Many had only one entry, but the display by Messrs. Ransomes was extensive. Prizes were also given for essays on agricultural subjects, for skill in plowing and for white and red wheat. From that day the scope of this annual show, as that of most others, has increased, and its form has been closely imitated in the British empire and foreign countries. Although Britain has become overwhelmingly industrial, its agricultural shows are superior in magnitude and excellence to any in the world.

The royal show has always been peripatetic, except in 1903, 1904 and 1905, when it was taken to Park Royal, on the north of London, with disastrous financial results. The prevailing principle in the selection of sites is to alternate populous districts with rural centres. Except when the weather has been unfavourable, the receipts from the first usually enable the society to bear the losses sustained in the second.

Several of the local shows are comparable with the royal shows, though smaller and of shorter duration. A similar variety of exhibit is seen in the shows of the Highland society, the Bath and West of England society, the "Royal Counties" and the "Three Counties" in the Welsh national, and in many of the larger county shows. Many of these, as well as the royal, have attracted large numbers of foreign buyers, especially from South America.

Most of these shows and the societies that sponsored them progressed, with some oscillations, until the depression years following World War I when it became apparent that they were too numerous and elaborate. Although such shows as those of the Suffolk, Lincolnshire and Cornish societies continued prosperous in the 1920s, a movement for the merger of local and county shows began. Yet the breed associations, more in Britain than in other countries, are the backbone of the shows and give no sign of decline.

The great additions to the scope of the shows in the 20th century were made not only with the idea of promoting agricultural science but to draw larger attendance and so provide funds for the proper objects of the societies. The royal show, which continues for five days, may occupy as much space as 100 ac., and the machinery, much of it in operation, is alone a great feature Besides almost all breeds of livestock and poultry, there are exhibits devoted to flowers and forestry, sections on education and science, and displays of rural crafts and the work of the women's institutes. A dairy is seen in action several times a day. Lectures and demonstrations of many sorts are given at intervals, and every afternoon, except on the opening day when most of the judging is done; horse jumping and harness competitions draw large crowds.

The fat-stock shows, held in November and December, and the dairy show, held in London in October, have flourished under urban conditions. As dairying took the lead over corn growing in British farming following World War I, the annual dairy show became a remarkable epitome of the science of dairying and of the quality of the dairy breeds. Of the winter fat-stock shows the three attracting the best entries are held at Norwich, Birmingham and the Agricultural hall at Islington in north London. From the first the Smithfield club has always emphasized the supply and breeding of meat in its London show.

**The Countries of the European Continent** also have vast agricultural shows. Among the more important are the Concours Général Agricole de Paris, the East Prussian Agricultural exhibition, the International Exhibition of the Cheese Industry and Trade of Italy and the General Association of Breeders National show in Spain.

**Agricultural Societies in the United States** were long an important means by which farmers effected mutual help and gained knowledge needed in solving technical problems. There is evidence of several ephemeral organizations of this sort during the late colonial period, but the two oldest of those still functioning (1946), namely the Philadelphia and the South Carolina societies for promoting agriculture, were founded in 1785. The Columbian Agricultural society, which aspired to national leadership, was begun at Georgetown, D.C., in 1809. These societies, together with other local and state groups modelled on them, were pioneers in agricultural education. They provided the public with accounts of the best agricultural practices abroad and the results of experiments conducted by their own members. Several of them endowed professorships in natural history, chemistry and agriculture. For the most part their membership consisted of men primarily concerned with public affairs rather than dirt farmers.

The incorporation of the Berkshire (Mass.) Agricultural society in 1811 marked the beginning of a new trend. Its founder, Elkanah Watson, was convinced that the societies should be organized by counties and on a more democratic basis. His success in developing the fair as the main educational medium for agricultural societies led to an organizational movement that was practically nation-wide. The allotment of state funds to county societies was an important factor in their rapid expansion, begin-

ning with New Hampshire in 1817. With the discontinuance of state aid, the number of societies declined, but there was a revival of interest in them in the 1830s.

Following an abortive attempt to effect a national association in the early 1840s, the United States Agricultural society was organized in 1852 by representatives of 23 states and territories to co-ordinate the work of county as well as state groups. Its membership included farmers as well as men prominent in political life. It held annual sessions and sponsored exhibitions and field trials. It was influential in securing the establishment of the United States department of agriculture.

The nature of the problems confronting the farmers after the Civil War resulted in new types of societies. A series of farmer organizations turned to political action as a main means of improving the agricultural situation (*see* AGRICULTURAL ORGANIZATION). Simultaneously, with specialization in farming, societies began to be organized according to the crops or livestock raised. The oldest horticultural society was started in 1829, and several states authorized boards of horticulture relatively early. It was not, however, until after 1875 that the interest in pure-bred livestock resulted in the organization of numerous breed associations that maintained registries and otherwise promoted their respective breeds. Similar organizations appeared for the various field crops, vegetables, fruits and nuts. With the progress of agricultural education and the sciences pertaining to agriculture, the technical specialists formed the American Society of Agronomy, the American Farm Economic association and similar professional organizations.

With the 20th century, county societies as visualized by Watson disappeared or limited their activities to the annual fairs. Even the state societies lost most of their former influence. Their place in the field of education was taken by boys' and girls' clubs, the county farm bureaus and similar units of the Grange and the Farmers union, and by local clubs devoted to community development.

**Agricultural Fairs** and exhibitions were an integral part of U.S. rural life for more than a century and played an important part in the progress of agriculture. The first fair is usually credited to Washington, D.C., where a series of three was begun in 1804. Although combined with sales, premiums appear to have been offered. After a brief lapse, the Columbian Agricultural society held a series of five fairs in Georgetown, D.C., beginning in 1810. It remained, however, for Elkanah Watson, a wealthy business man who had retired to Pittsfield, Mass., for "rural felicity," to demonstrate and sell the values of fairs as a distinctive educational institution in the U.S. In 1807 he exhibited two Merino sheep on the village green, and three years later he induced his neighbours to form a society, pledged to hold an annual fair. Thus the Berkshire Agricultural society became the first permanent fair association in the United States.

The movement for county agricultural societies and fairs spread fairly rapidly, and Watson was active in assisting in their organization. In 1819 the New York legislature appropriated $20,000 for two years for the county fairs of that state, and after a few years other states generally provided modest subsidies for their fairs.

The fairs prior to 1870 were primitive and crude. Those held by county societies usually lasted two days and those by states three days. Few of the fairgrounds were more than 10 ac. in extent and usually not more than 1 or 2 ac. State fairs were rotated from city to city. Inadequate transportation was a drawback. For instance, low water on a navigable river often dictated failure. The inadequacy of funds was also a dominating factor. The premiums were modest, and the highest awards were usually certificates of membership in the society. Agricultural books and subscriptions to agricultural periodicals were also given as awards. In many lines the exhibits were meager and poorly classified, and the judging was done by impromptu committees. Plowing matches were held, but amusement features were subordinate. The annual address had a leading place in all programs. Horace Greeley was probably the most widely known and celebrated lecturer. Abraham Lincoln's address before the Wisconsin State fair at Milwaukee in 1859 may well have helped win him the presidency.

The Civil War had an unsettling effect on the fairs. The grounds were usually used as places for assembling and quartering troops and the Indian uprisings and invasions were disturbing. The years following 1870, however, brought revival and change. The country was experiencing a vast expansion of agricultural production Class-conscious farmer organizations sprang into being. The land-grant colleges became the established medium of agricultural education, and the work of the federal department of agriculture was extended.

In consequence, the main educational functions of the fairs came to be carried out in co-operation with the colleges and the farmers' institutes. The lectures and evening sessions were discontinued. The depressions and the competition of the world expositions cut the attendance. The amusement features came to the fore. Horse racing, velocipedestrianism, balloon ascensions and eventually auto races became major attractions. Circus stunts and spectacles such as locomotive collisions were added. Night shows featuring pyrotechnics were popular. Many of the fairs were extended to cover a week or more. The problem of what to emphasize on Sundays was solved by including sermons and musical concerts.

After 1910 there was a revival of interest in the educational features of the fairs. Boys' and girls' club work and farm bureau activities contributed immeasurably to this end. Judging contests, home economics, visual instruction, health clinics, agricultural engineering demonstrations and pageants received considerable attention. Many of the larger associations systematized their organization and hired expert managers. Including regional, state, district, county, community, township, school and street fairs, the number is around 3,000, and the range in character of exhibits, time and location is large.

The first great show of more than local importance, known as the American Fat-Stock show, was established in 1878 by the Illinois state board of agriculture and was held annually in Chicago from that time until 1897. It was the outgrowth of the desire of a number of stock breeders and feeders, as well as men interested in horses and swine, to stage a show in keeping with the progress of the purebred livestock industry. The show was patterned after the famous Smithfield Club show in England and flourished for many years until political influence and inadequate support caused its failure in 1897. Three years later, the present International Live Stock exposition was organized. It held its first show in Dec. 1900, at the Union Stock Yards in Chicago. It was founded largely through the efforts of a group of admirers of purebred animals which included such famous leaders as Robert B. Ogilvie, Mortimer Levering, William E. Skinner, Alvin H. Sanders, John Clay and John A. Spoor. Profiting by the experience of the old Fat-Stock show, the new organization laid plans for a great educational institution free from political favoritism. Following closely the ideals of the founders, succeeding directors have made the International the leading exponent of a great movement for the improvement of livestock and crops in the U.S. The International has been held annually in Chicago ever since its organization, except in 1914 and 1915, when it was omitted because of the presence of foot-and-mouth disease in the United States. Staged usually during the last week in November and the first few days in December, a time when all other fairs and shows have been completed, the International draws the year's prize-winning draft horses, beef cattle, swine, sheep, grain and hay exhibits from the United States and Canada. The organization owns its own grounds, covering 500 paved acres. Joined to the many barns and other buildings housing the show stock is the amphitheatre, seating 12,000 visitors and enclosing a tanbark arena 238 ft. long. There the finest livestock in North and South America are paraded before the eyes of leading judges of North and South America and Great Britain. Carlots of fat stock and individual dressed carcasses are exhibited. Standards have been set by this show. Year by year this institution has expanded until all major phases of U.S. agriculture are embraced within its scope. While the display of breeding and fat livestock is still the cornerstone of the exposition, many educational and

entertainment features have been added from time to time. The evening horse shows, including ponies, hunters and jumpers, saddle and light harness horses, have won world fame for the quality of the entries. The various state colleges have long been exhibitors of some of the finest livestock in all classes and the annual livestock judging contest for agricultural college students is of far-reaching importance as an educational feature. Within the last decade 1,000 or more farm boys and girls have attended the International annually as a reward for achievement in club work in agriculture and homemaking. Classes for baby beeves and lambs raised and fitted for show by these young farmers have formed one of the new and important attractions, and the livestock judging contest, open to champion junior judging teams from every state, is another innovation. Interest in feeding, fitting and showing livestock is encouraged by a large class of awards for herdsmen, caretakers and other helpers.

While the International is the livestock classic of the year, there are other shows of great importance to the regions in which they are held. The exhibits at such shows are often on a par with those at the International, although they draw from a much more limited territory. Such shows as the American Royal Live Stock show held annually at Kansas City, Mo., the Pacific International Live Stock exposition at Portland, Ore., the Southwest Exposition and Fat Stock show at Ft. Worth, Tex. and the National Western Stock show at Denver, Colo, are important shows held prior to the International. From these it draws many of the winning animals. The great show of the east is the Eastern States exposition held annually at Springfield, Mass., from its organization in 1916. Dairy cattle are the big feature of this show, although there are always excellent classes of all breeds of beef cattle, sheep, swine, light horses, hunters, jumpers and ponies.

The National Dairy show is primarily a show for the advancement of the dairy industry, although some classes are held for horses. Its livestock exhibit consists of 1,000 or more of the finest dairy cattle of all breeds in the U S. It is by no means limited to the livestock end of the industry. Machinery and equipment for the creamery, the distributing plant and every other phase of dairy manufacture, form a large part of the attraction and add to the educational value of the show. The show was first held in 1906 in the Chicago Coliseum. The success of this first venture resulted in the organization of the National Dairy association and the continued success of the show thereafter. It is a much travelled show, having been held in Chicago, Ill.; Columbus, O.; Springfield, Mass.; Milwaukee, Wis.; Detroit, Mich.; Indianapolis, Ind.; St. Paul, Minn.; and Memphis, Tenn. Another important dairy show is the Dairy Cattle congress held annually at Waterloo, Ia. The National Swine show is the leading show in the world of breeding swine and is devoted exclusively to this branch of the livestock industry. While in point of numbers it is often exceeded by some of the larger state fairs, no other swine show draws so many champions of the various breeds from all parts of the continent. It was organized by the National Swine Growers' association primarily as a breed-promotion institution, holding its first show in 1916 at Omaha, Neb. It has also travelled, having at different times been held in Cedar Rapids, Ia., and Des Moines, Ia. In 1921 it moved to Peoria, Ill., where the association now owns its buildings and grounds.

Poultry shows have been held in the United States for more than 50 years. Thousands of shows of varying sizes are held annually, small towns and communities having their local shows and many state fairs having poultry exhibits also. Large state shows are held later in the season and are followed by regional or international shows. The leading poultry show is the Madison Square Garden Poultry Show at New York city, where it has been a regular event from 1870. Thousands of birds are exhibited in individual cages designed to show them to advantage. Pigeons, bantams and every other variety and breed of feathered domestic fowl are included. The Boston show was the first large poultry show in the U.S., having been started in 1865. It is well balanced and in some respects is better than the Madison Square Garden show. Other poultry shows of nation-wide interest are held in various cities.

There is scarcely a branch of the agricultural industry that does not have some show of more or less national scope. Special shows are held by rabbit breeders and fanciers, by kennel clubs and by organizations interested in bees and in songbirds. There are shows exclusively for horses of certain breeds, for fruits and vegetables and for flowers. The Society of American Florists and Ornamental Horticulturists holds the National Flower show at a different place each year. The International Flower show is held annually in the Grand Central palace, New York city The American Orchid society holds a large show, usually every other year, at Madison Square Garden. Countless other flower societies exhibit their new products in various local and regional shows. Obviously all these exhibits are of immense value to specialists as well as amateur breeders and growers in making progress in their profession.

**Canada.**—Approximately 500 fairs are held annually in Canada, most of them being provincial or local Probably the first was at Niagara-on-the-Lake (then Newark, Ont ) in 1798 The most important is the Canadian National exhibition at Toronto. Held usually in September, it includes practically every branch of agriculture and allied industries and emphasizes educational features.

Another fair of note is the Royal Agricultural Winter fair, patterned after the Royal Agricultural society's show in England. It was first held in 1922 on the grounds of the Canadian National and grew rapidly. This annual show is usually in December and is limited to livestock, grain, hay and other farm products. Its entries are drawn from Canada, the United States and other countries.

Other agricultural fairs of note are the Central Canada exhibition at Ottawa, the Calgary Exhibition and Stampede, the Old Winter fair at Guelph, the Provincial exhibition at New Westminster, the Quebec Provincial exposition, the Provincial exhibition at Regina and the Great Eastern exhibition at Sherbrooke

**South America** holds many local or regional fairs and expositions every autumn, but the principal one is the Argentinian *Exposición Nacional de Ganadería,* usually called the Palermo show. This exposition ranks with the leading livestock shows of the world. It was inaugurated in 1875, with but 18 head of horned cattle by the Argentine Rural society (founded in 1866). Its early progress was irregular and in some years no shows were held because of financial and other difficulties. With the growth of the livestock industry in Argentina and other South American countries it finally became established and is now held annually in the autumn at Buenos Aires, where the society owns grounds and buildings near the fashionable Palermo suburb. The Palermo show is principally a beef-cattle show. There are often from 1,000 to 1,800 head of Shorthorn bulls in the show rings. The Shorthorn classification is perhaps the most elaborate show-ring exhibit to be found in any livestock show in the world, there being as many as 29 classes, in which the animals range from junior yearlings to 3-year-olds. The great number of classes is due to the separation of the animals into groups differing in age by from 15 to 30 days, whereas in other countries most show classes are from 4 to 8 months apart in age. Another unique feature is the compulsory auction of practically all animals exhibited, the purchaser paying a selling commission of 6%. The commission rate is doubled if the owner buys back his own exhibit. The auctioning of the grand champion bull is the outstanding attraction and has become an event in the social season. A week or ten days is often required to complete the auction after the closing of the show. Besides Shorthorns, other breeds are shown in great numbers and in good quality, as are horses of both light and draft breeds, sheep, swine, poultry and other agricultural exhibits. Dairy cattle are also an important feature of interest. The exhibition grounds are beautiful and in perfect condition and the buildings are elaborately designed and well-arranged around the show rings to permit all judging to be done in the open.

Two other important livestock shows in South America, both of which are held in Uruguay, are the National Live Stock and Poultry exposition at Montevideo, and the Live Stock and Poultry exposition at Salto.

The exposition at Montevideo is under the management of the Rural Society of Uruguay and is largely a cattle show, but there are usually good classes of sheep, swine, dairy cattle and horses. The Salto show is principally a cattle show, the Hereford breed predominating.

**AGRICULTURAL STATISTICS.** Agricultural statistics have a vital, basic significance in a nation's social and economic welfare. The practical use of statistics of production, supplies and movements of the products of agriculture has been highly developed by business and governments. The world-wide depression of the early 1930s, and the ensuing increased activity of governments in aiding or controlling agricultural production and marketing added impetus to the further development and use of agricultural statistics War emphasizes still further the fundamental national importance of maintaining adequate sources of information on agricultural resources, potentialities and deficiencies.

The regular systematic collection of statistics relating to agriculture began early in the 19th century. Annual estimates of agricultural production were begun in France in 1815. In the United States, agricultural census taking began in 1840, and annual estimates of production in 1866.

In England it might be claimed that the first agricultural statistics were those collected in the 11th century in Domesday Book, which included a record of the use of all land then under cultivation. Gregory King estimated the use of land and the production of England at the end of the 17th century. But it was not until in the 19th century that the state undertook, as an ordinary function of administration, the annual collection of statistical information about agriculture. In the early part of the 19th century spasmodic attempts were made from time to time in different parts of the country to collect agricultural statistics. In 1855 a committee of the house of lords reported in favour of uniform and compulsory returns and in 1864 a resolution was passed by the house of commons demanding the immediate establishment of a national system of agricultural statistics. No legislation was passed but the board of trade gave effect to the wish of parliament and established a system of annual returns from every occupier of agricultural land of the acreage of crops and number of livestock on each holding. The returns were first obtained in 1866, and in 1884 they were supplemented by the collection of estimates of the year's yield of the principal crops. The responsibility for the collection of all agricultural statistics was transferred from the board of trade to the board of agriculture soon after its establishment in 1889.

The most systematic attempt to provide agricultural statistics by private enterprise was that made by Lawes and Gilbert in their calculations of the production and consumption of wheat in the British Isles. These were started in 1852 and continued annually until official estimates of the yield of wheat and other crops were begun 32 years later.

In many countries the field of agricultural statistics has been extended to include the collection of price data, estimating cost and income, and securing data relating to the occupiers of and the conditions of living on the land.

The International Statistical institute and the International Institute of Agriculture have been influential in extending the systematic collection of statistics relating to agriculture in many countries in recent years. About 1930 an effort was made to encourage countries which had not developed systematic census taking, to take a census which could be co-ordinated with the censuses of other countries so as to obtain a more complete world-wide coverage of agricultural production. The most significant development in agricultural statistics in recent years is the use of current and historical data relating to prices, supplies and economic conditions affecting the demand for agricultural products, to forecast or estimate probable prices in the market or the income from the products of the year. Such analyses are being used extensively in the U.S. and to some extent in other countries as a basis for formulating programs and policies relating to agriculture.

**Systems of Collection.**—Most of the larger nations, and many private business groups, maintain trained organizations and well developed methods for gathering agricultural statistics In the U.S., the department of agriculture issues comprehensive regular, periodic and special reports that are accepted by business generally as authoritative. The department's monthly forecasts and reports on crops and markets are awaited by all major lines of business and are quite a material factor in determining business activities. These statistical reports are gathered and compiled by a trained staff. In addition the department maintains specialized services throughout the country, such as those of grain inspectors at 135 shipping points and meat inspectors at packing centres The quinquennial census also provides comprehensive data and serves as a valuable test-check.

There are a number of private agencies that supply agricultural statistics which are accepted as authoritative These usually relate each to a specific commodity such as cotton, wheat, sugar, etc Outstanding among such statistical organizations is Broomhall's, Liverpool, whose forecasts and reports on grain are standard market information throughout the world. The New York Cotton Exchange, and other large commodity markets maintain permanent statistical organizations to supply information on production and distribution.

**Statistics of World Agriculture.**—Nearly all countries have been signatories to the International Institute of Agriculture, Rome, which supplies regular monthly and annual reports and special studies on the major crops, livestock and livestock products of the entire world, excepting chiefly U.S.S.R. and China, for which information is fragmentary. The Institute issues a monthly *International Review of Agriculture*, which contains official reports on conditions of agricultural production in nearly all countries, forecasts of crop yields and size of harvests. The Institute's *Yearbook of Agricultural Statistics* is an annual summary of world agricultural production and, like its monthly reports, is printed in English and French.

The average annual production (1935–39) of four principal cereal crops in major producing areas was as follows, the figures representing millions of bushels.—

| | Wheat | Rye | Barley | Oats |
|---|---|---|---|---|
| [illegible] (Except U.S.S.R.) | 1,626 | 898 | 719 | 1,745 |
| [illegible] | 1,086 | 54 | 331 | 1,384 |
| [illegible] | 143 | 1* | 121 | 22 |
| Asia (Except U.S.S.R.) | 1,442 | | 768 | |
| [illegible] | 281 | 10† | 28 | 61‡ |
| Oceania | 177 | 0.2 | 13 | 27 |

*University of South Africa only
†Argentina only
‡Argentina, Chile and Uruguay only

Statistics of farm livestock are less complete than those of crops and are in many countries collected infrequently at irregular intervals. The following table shows approximately the world's totals of the principal meat animals in comparison with the human populations of the six great world areas, in thousands.

| | Population* | Cattle† | Sheep† | Hogs† |
|---|---|---|---|---|
| Europe (Except U.S.S.R.) | 398,287 | 110,200 | 129,200 | 81,200 |
| [illegible] | 170,467 | 48,500 | 70,080 | 23,900 |
| [illegible] | 182,409 | 96,000 | 59,700 | 61,300 |
| [illegible] | 91,192 | 105,600 | 101,000 | 31,200 |

| Africa | 158,408 | 61,100 | 100,600 | 3,300 |
| Oceania | 10,610 | 18,000 | 143,900 | 2,100 |

*International Institute of Agriculture, 1938 figures
†Reports of U.S. Department of Agriculture, Office of Foreign Agricultural Relations, averages for 1936–40

Unfortunately no statistics of any reliability are available for China (pre-eminently an agricultural country). The annual value of pigs reared in China must be enormous and cattle and horses are everywhere in evidence; but the unsettled state of the country has made records difficult to obtain.

The distribution of the animals and their relative importance as indicated by their density are shown in the following table.—

| Country | Number of livestock per 1,000 hectares* | | | |
|---|---|---|---|---|
| | Horses | Cattle | Sheep | Pigs |
| United States | 14 0 | 85 8 | 68 4 | 57 4 |
| United Kingdom | 45 6 | 363 6 | 1,091 3 | 181 7 |
| Canada | 3 1 | 9 5 | 3 8 | 3 9 |
| Germany† | 73 0 | 435 6 | 99 7 | 506 6 |
| France | 48 9 | 286 8 | 181 4 | 129 2 |
| Italy | 25 5 | 247 3 | 305 3 | 94 8 |

*1 hectare=2 47 [illegible] do not include Austria or the Sudeten; do include Saar. [illegible] 1938

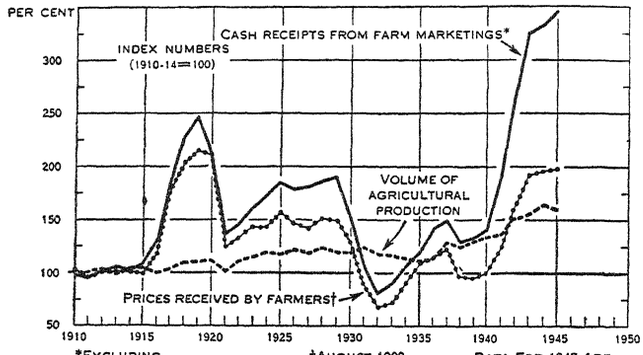
**Statistics of British Agriculture.**—For many years statistics of British agriculture were collected by the Board of Agriculture for Great Britain and the Department of Agriculture for Ireland. In 1912 the Board of Agriculture for Scotland was established and took over the collection of statistics in that country. When Ireland was divided, separate departments were set up for Northern Ireland and Eire so that there were then four departments responsible for the agricultural statistics of the British Isles.

During World War II food production was greatly expanded as indicated by the following figures of acreage and production:

| Crop | Acres (thousands) | | Production (million bu.) | |
|---|---|---|---|---|
| | 1939 | 1944 | 1939 | 1944 |
| Wheat | 1,766 | 3,220 | 61 4 | 117.2 |
| Barley | 1,013 | 1,973 | 41.6 | 81 8 |
| Oats | 2,427 | 3,656 | 140 2 | 206.7 |
| Potatoes | 704 | 1,421 | 194 7 | 368.1 |

The numbers of farm livestock, including poultry, in the United Kingdom in 1944 were as follows: Horses and colts, 918,000; cattle and calves, 9,501,000; sheep and lambs, 20,108,000; pigs, 1,867,000; chickens, 50,301,000; ducks, 3,004,000; geese, 905,000; turkeys, 995,000.

Particulars of other crops, and statistics relating to agricultural output which are not included in the annual returns are obtained from time to time in connection with the census of production (*see* AGRICULTURE, CENSUS OF).



**Statistics of Agriculture in the U.S.**—The averages (1934–43) of the annual estimates of the area and production of some of the principal crops in the U.S. are presented as follows:

| | Acres harvested (millions) | Production (million bu.) |
|---|---|---|
| Wheat | 53.8 | 789 1 bu |
| Corn | 91 2 | 2,433 1 bu. |
| Barley | 12 0 | 273 5 bu. |
| Oats | 35 8 | 1,068 4 bu. |
| Cotton | 25 6 | 12.3 bales |
| Tobacco | 1.5 | 1,392 0 lbs. |
| Potatoes | 3 0 | 375.1 bu |

The crop areas seeded and harvested in the United States vary considerably from year to year. The area of wheat harvested is in many years considerably less than the area seeded because of heavy winter freezes, droughts and diseases. The acreage losses from the seedings of the other crops are as a rule small. The estimates given above represent the areas harvested. The 10-year averages are presented as a better indication of areas and yields than the estimates of any one year which may be affected significantly by droughts or other conditions causing considerable changes in either the area harvested or the outturn of the crop.

In recent years the department of agriculture has extended its estimating service to include intentions to plant crops. The data are collected in advance of seeding so that each individual farmer may have some information as to what farmers generally are planning to do for the forthcoming season. These data are useful in determining the marketing policies of both private and co-operative distributors. They are used by the federal government also in determining production and marketing policies. Averages of the annual estimates for the 10 years (1935–44) of the numbers of the most important species of livestock on farms in the U.S. are: horses and mules, 14,729,000; dairy cattle, 25,656,000; all other cattle, 45,381,000, sheep, 52,768,000; hogs, 55,300,000, chickens, 447,889,000

The numbers of animals in the U.S. vary considerably from year to year and in cycles of years. The production of hogs in the U.S. is such an important factor in the agricultural economy of the country that an elaborate statistical service has been developed for this industry. In addition to estimating the number on farms as of January 1, the department of agriculture estimates in June and December of each year the number of pigs farrowed and the number of sows bred or to be bred. These estimates of breeding and farrowing are designed to provide a basis for estimating the number of hogs likely to be marketed and the pork production in the season ahead. Reports from slaughter establishments provide a basis for estimating the actual production of pork. The dairy and beef-producing industries of the U.S. are likewise important, but the changes in the numbers of cattle on farms are less variable from year to year and have longer production cycles which can be anticipated to a considerable extent from supplies of feedstuffs and the relation between prices of feedstuffs and of the animal products.

COURTESY, U.S. DEPT. OF AGRICULTURE

**AGRICULTURAL PRODUCTION, PRICES AND RECEIPTS, UNITED STATES, 1910-45**

Estimates of income have been developed as measures of the buying power of farmers, as indications of how economic conditions generally affect farmers. Also, the relative importance of the several agricultural enterprises of the country is best indicated by the estimates of income received from these enterprises.

The average income received from principal farm products in the five years (1940–44) follows, in millions of dollars:—dairy products, 2,305; cattle and calves, 2,116; cotton, 1,147; hogs, 2,013; chickens and eggs, 1,509; wheat, 765; tobacco, 459; sheep, lambs and wool, 414; corn (maize), 479; potatoes, 159.

The importance of corn (or maize) and other feedstuffs is, of course, not indicated by estimates of income received directly from those crops. The production of such crops comes to market mostly as livestock products. Consequently, the variations in prices of feedstuffs have little significance in the income of the country. They are an indication of the relation of supplies of feedstuffs to the demand for them and affect costs of production as between the farmer who raises the feedstuffs to sell and the farmer who buys them for feeding.

The effects of recovery and of World War II on the agricultural economy are reflected in the annual estimates of cash income from marketings of farm products. Annual estimates[1] for the years 1932–44 follow, in millions of dollars: 1932, 4,743; 1933, 5,314; 1934, 6,334; 1935, 7,086; 1936, 8,367; 1937, 8,850; 1938, 7,686; 1939, 7,877; 1940, 8,343; 1941, 11,157; 1942, 15,316; 1943, 19,340; 1944, 20,228.

The receipts from the sale of farm products are estimated currently for each month, on the basis of prices reported as received by farmers and estimates of marketings by states as well as for

[1]These estimates do not include government payments, nor the value of products consumed on the farm where produced

the country as a whole. The expenditures for production annually are also estimated to provide a basis for determining annual net returns. (E. J. WG.; O. C. S.; R. H. R.)

**AGRICULTURAL WAGES.** The payment of wages for agricultural labour in England began with the disappearance of serfdom. The coming of the Black Death or plague in the middle of the 14th century hastened the growth of the wage system and stimulated a rise in wages. The Statute of Labourers was enacted in part to check this rise. The change to the wage system came much later in eastern Europe. Even today most of the wages are paid in kind in some regions. The money wage system was carried into all of the English colonies, in many places in combination with a system of indentured servants and with slavery. When slavery was abolished in the United States, a wage system would seem logically to have followed. The Negroes, however, were not yet ready for this step and presently most of them were working under a cropper system in which they lived on plantations in cottages furnished by the owner, used equipment furnished by the owner, and received their compensation in the form of a share of the crop. Those familiar with this system still look upon it as more nearly a wage relationship than a landlord-tenant relationship.

A major complication in measuring wage-rate changes is that in all countries a good part of the actual compensation of the farm worker is in the form of board and lodging, in the case of single men, and of food and fuel for the use of the family and the use of a dwelling, in the case of married workers, plus perhaps the right to use a plot of land or to keep some livestock on the employer's land. In central Europe these allowances are known by the term deputat; in the United States as perquisites. Where wages are regulated, official valuations may be placed upon these extras; otherwise the wage-reporting agency must make a rough estimate of their value. The basis of valuation is invariably what these allowances are worth in the immediate neighbourhood. Commonly they would cost very much more if they were being purchased by an industrial worker in the city. The listing of wages is also involved by the fact that the period of hiring may be the whole year, the summer or winter half-year, a few months during the spring and early summer, or from day to day. The day labourers may be casuals hired for a few days now and then or workers hired regularly by the day for a considerable period. The most numerous in the first group are the piece-rate workers, who help especially with harvesting. The year-round rates reported are commonly for more experienced workers carrying more responsibility. Many of them are part-managers of the farm enterprise, perhaps in some such capacity as herdsman or shepherd. The farm servant in Great Britain and several other countries, and the deputatist of Germany and other countries on the continent, are typically year-round workers on a somewhat lower wage scale. From the point of view of income, only the data for the year-round workers are adequate. One has no means of knowing how much of the rest of the year the seasonal workers and day hands are without employment.

**History of Wages.**—Money wages need to be converted to real wages before they are significant. This can be done crudely for the United States since farm wages were first assembled in 1866 by adjusting them for the changes in the general price level. The money wages increased 20% from 1869 to 1897, and the real wages 135%. Then came the period of rising price levels ending in 1915, during which money wages rose 58% and real wages only 10%. The final effect of World War I was a rise of 85% in real wages by 1925–29. Real wages in industry rose 150% to 1897, held even until 1915, and then rose 63% to 1925–29. The lag in both agricultural wages and industrial wages in 1897–1915 was due mainly to the inability of wages to move as fast as prices. Wages in wartime Europe lagged in the same way. The wartime shortages of labour broke this lag. Farm wages did not rise as much as industrial wages in the recovery period after 1933.

For a longer series of wage changes, England can be taken as an example, but real wages for such series will have to be expressed still more crudely in terms of wheat. In terms of money, agricultural wages in England rose from 4*s.* per week in the 13th century to 46*s.* by 1775, but in terms of wheat this represented an actual decline from 126*£* to 71*£*. This is the reason for Thorold Roger's statement in his *Six Centuries of Work and Wages* that the 15th century was "the golden age of the English labourer." By the end of the 19th century the purchasing power of wages for wheat had returned only to the 15th century level. All through the 16th to the early 19th century, weekly wages in wheat remained around 71*£* to 91*£*. The movement from then until World War I was roughly the same as in the United States. In 1914, a week's farm work in Great Britain bought 4.2 bu. of wheat. Money wages had advanced 24% from 1900 to 1914, but real wages 15%. Wages rose less than the cost of living during the war, and the Agricultural Wages' board in 1920 set wages at levels from 42*s.* to 56*s.* in the various counties. The passage of the Repeal Act of 1921, following the sharp break in prices, wiped out this board, and the wages and voluntary conciliation committees set up in its plan were not very effective. Wages fell to 28*s.* by 1924, compared with 18*s.* in 1914. This meant a decline of 12% in real wages. The new boards set up under the Agricultural Wages Act of 1924 had raised wages 3½*s.* by 1931 while the cost of living was declining. Real wages as a result rose one-fifth in this period.

For the years after 1928, much more adequate data were assembled by the International Labour office, and published first, for 27 countries, in the *International Labour Review* for Nov. and Dec. 1934. The latest release, in the *Yearbook of Labour Statistics, 1945–46,* extends this series through 1937 for 21 countries, through 1942 for 17, through 1945 for 12 and into 1946 for 7. Money wages declined in all these countries except Chile in the big depression of 1930–35, but by varying amounts. The lowest year was 1933 in the aggregate, but ranged from 1931 in Japan to 1937 in India. In five countries, including the United States and Canada, the break was around one-half; in Australia, New Zealand, Japan, India and Italy, around 30%; and in the western European countries, between 4% and 11%. All but three in this last group either had agricultural wage boards or were supporting farm prices with heavy import duties and the like.

In the period leading up to World War II, farm wages generally rose. The gains were smallest, around a fifth or less, in the exporting countries, like the United States, Canada and Australia, and most in the countries of western and central Europe, from 30% to 50%. The severity of the continuing unemployment to 1935 was no doubt also a factor, and presently in Europe, the amount of preparation for war. If depression losses and recovery gains are balanced against each other, farm wages in Canada and the United States in 1940 were around 30% below the 1929 levels; in Australia and Mexico, 10% below; in Great Britain, 6% higher; and in Norway, France, Ireland, Sweden and Denmark, from 10% to 40% higher respectively in the order named.

No doubt the extent of the general price deflation in the depression, and reflation afterward, was also an important factor in these wage movements. Clearly the general price level movements were the main reason for the difference between countries in the wage increases during World War II. In the International Labour office tables, the index numbers for 1945 range, with 1937=100, from 138 in New Zealand, 159 in Australia, 203 in Sweden and 210 in Great Britain, where prices and wages were kept fairly well under control, to around 250 for the United States and Canada, to around 300 for Denmark and Norway, and 500 for France and Finland.

**Wage Differences.**—Wage differences between countries are best indicated by taking the data on money wages of the International Labour office for some nearly normal year, like 1928, and reducing them to a common purchasing power basis, as in the table on page 391I.

The wage taken as representative in each case is the wage without board and lodging of an adult male ordinary day labourer. The conversion to shillings and pence is in terms of the average rate of exchange for the year 1928. The prices for wheat and other products are the internal wholesale prices at a principal market in the country.

Taken at their face value, the differences appearing are very

| Country | Daily wages | Wages in British money | Wages in wheat (bu.) |

*No wheat prices available. †All figures are for 1931. ‡All figures are for 1932. ¶All figures are for 1929. §Figures for money wages are 1928, for wheat wages, 1932. **All figures are for 1930.

large: from 4 pence in China to 16 shillings in Australia. They are in order with what we know about relative density of population and other significant factors in the various countries; but the range is no doubt exaggerated in terms of real wages. The number of yen equal to a shilling in the foreign exchange market buys much more in the way of food, clothing and shelter in Japan than the number of kroner equivalent to a shilling in Sweden, and even more so than the number of cents equivalent to a shilling in the U.S. market. The comparison in terms of quantities of wheat bought by a day's wage is subject to the serious objection that the price of even as staple a commodity as wheat is subject to special influences in each country; for example, to very high tariffs in France, Italy and Switzerland. Wheat prices in Canada, Australia and the United States are on an export basis, which means that they are less than the world price by the amount of the cost of transportation.

The International Labour office reports male and female wages separately where available; also wages of "permanent," "seasonal," and "daily" workers. Female wages in 1928 averaged about 70% of male workers. Wages of seasonal and day workers are generally higher than annual rates. In the United States, for example, a day labourer would have needed to work only 240 days in 1928 to earn as much as a year-round labourer without board and lodging; in Japan, 200 days.

The wage differences between sections of any one country may be fully as large as those between whole countries. The range within France in 1928 was from 16 francs per day for regular day labourers in Dordogne to 27 francs per day in Loiret; in Italy, from 0.66 lire in Calabria to 1.59 lire in Emilia. The total wages of the deputatists (men) in 1928 were 1,619 zlotys in south Poland and 2,263 in west Poland. In the United States the range in the period 1925–29 was from around $25 per month in the southern states (with board and lodging) to more than $50 a month in some of the western states. These differences in the U.S. are closely correlated with such factors as natural resources and capital goods per worker, and in turn with the net farm income per worker. Associated with these circumstances are such factors as density of population, type of agriculture, alternative employment and the like. The high wage rates reported in some of the eastern states are much affected by competition with city employments. Almost everywhere the level of agricultural wages appears to be lower than that of industrial workers, particularly than that of skilled industrial workers. The explanation commonly offered is that the surplus population of the farms does not move to the cities rapidly enough to equalize returns.

**Wage Regulation.**—Wages were controlled in one way or another in England all the way from the Black Plague until 1835. The controls were largely locally administered and generally in behalf of the landed gentry, and had the effect of shifting to Poor Law relief part of the cost of maintaining farm labour. Similar controls commonly followed the abolition of serfdom on the continent. Individual bargaining replaced these controls with the passing of mercantilism in one country after another in the 19th century. Controls in behalf of farm labour began in the early 20th century; for example, in England in 1917. In North America, the new Mexican constitution in 1917 provided that minimum wage rates should be fixed for all the workers. Estonia provided for fixing minimum wage rates in an act of 1921, and Hungary, Uruguay and Argentina in acts of 1923. The present form of public wage fixing in England was provided in the Agricultural Wages Act of 1924. It can be said of the wage-fixing legislation enacted in the war and postwar years that its general purpose was to raise agricultural wages and improve the condition of agricultural workers. But much of it was induced by pressure from agricultural unions. An immediate purpose was to remove the causes of disorder and conflict between the employer and worker groups. It is proper to state that in a number of the countries agricultural wages are now adjusted mainly by collective bargaining. A large proportion of the labour may be outside the union, but the union dominates the scene.

In the Netherlands, for example, collective agreements increased from 11 covering 742 farms in 1918, to 326 covering 20,700 farms in 1936. By 1937 the wage rates of 30.000 Swedish workers were covered by trade union agreements. Collective bargaining is the device used for general wage adjustments also in Denmark, France and Norway. This system was well developed in Germany in the postwar years under the republic and in Czechoslovakia and Poland before 1938.

In Scotland the Farm Servants union insisted upon this method of wage adjustment until July 1937. It then secured the adoption of a plan of public wage fixing similar to that prevailing in England and Wales. As a matter of fact, wage determination by collective bargaining and by public wage fixing are not as clearly distinct as the foregoing statements indicate. The two methods are frequently made to supplement each other. Thus in Italy the wages are negotiated by collective agreements, but the Charter of Labour requires that the wages so determined apply to all workers whether organized or not. In the Netherlands the employers are required to negotiate wages with the workers' organizations and if necessary an arbitrator makes a compulsory award. In Australia and New Zealand the process of public wage fixing takes the form of calling the workers' organization and the employers' organization before an arbitration court, holding a hearing, and then establishing a rate. Even the procedure of England and Wales, which is clearly designed as minimum wage fixing, sets up local wage-fixing boards upon which the workers' organization and the employers' organization constitute all the board except for a small number of outside members appointed by the minister of agriculture.

The Central Agricultural Wages board has no power to influence the level of wages fixed by the local wage boards. The Irish Agricultural Wages Act of 1936, in contrast, gives to the Central Wages board the authority to fix the minimum wage rates, but only after consultation with the local wage committees upon which employers are represented. The Joint Labour committees set up in France on a regional, department and local basis under the order of July 7, 1946, were constituted about like those in England and function in a similar way. The wage boards which functioned in parts of the United States in World War II had little or no union or even employee representation on them, farm labour being very little organized in the United States.

The reason commonly advanced for having employer and employee organizations participate in the wage-making process is that the wages fixed are not likely to be accepted unless these groups help make them. The objection, of course, is that the unorganized employers and employees are required to abide by wage determinations made by organized groups that often are only a small minority. If, however, it is the policy of the country to encourage the unionization of agricultural labour, such an arrangement may well have the effect of bringing most of the employers and workers into it.

Hours and working conditions are commonly regulated along with wages. In England the hours set by the different county boards ranged in 1937 from 48 to 60 per week, with an average of 51 hours. Regulations also provide for extra pay for overtime

and Sunday labour, but these are not always enforced. The Holidays with Pay Act of 1938 provided for 7 days of holiday for farm labour, but not more than 3 days at a time. The New Zealand Agricultural Workers Act of 1936 incorporated in it the Accommodation Act of 1908 which stipulated certain standards of first aid, housing, laundry and food storage space for agricultural workers. Illustrating the form that wage regulation may take when modern forms of regulation are imposed upon relic social organizations are the decrees issued by the Bolivian government in May 1945 providing for setting up an Indigenous Labour Code limiting to 4 days the labour that can be required of the "colones" on the landowner's estate as payment of rent, and giving the colones full right to sell their own produce

A development since 1930 in several countries is that minimum wage rates have been tied to arrangements for improving the prices of farm products The sugar growers of the United States must pay certain rates to share in the benefits of the Agricultural Adjustment act The New Zealand butter and cheese act of 1937 has a similar stipulation. Swedish sugar factories may conclude contracts only with farmers who agree to pay the wages named in the collective agreements in force

**AGRICULTURE: A GENERAL SURVEY.** Agriculture is so primitive and fundamental an art, the beginnings of which so far precede any documents, that any attempt to write its earliest history becomes a matter of surmise and unverifiable conclusions from general principles It is reasonable to suppose that prehistoric hunter man began by learning to tame the young of certain species, which proved to be fertile in captivity and could be attached to his wanderings. At probably a later stage tribes that gathered certain grains of food value began to make provision for future years by scattering a portion of the seed and effecting some rough clearance of the soil. They took the desirable grains with them in their wanderings and by sowing them they learned to become independent of return to the original centres of growth. When any remains of the early settlements emerge, they reveal evidence of animals and cultivated plants For example, predynastic tombs in Egypt, an early Sumerian house in Mesopotamia (3500 B.C.), and lake dwellings in Switzerland and Italy associated with neolithic man, have yielded grains of wheat of a comparatively advanced type, which must have been preceded by long ages of culture. Flax and barley were also grown. It is significant, however, that no wild species can be assigned as the origin of any of our widely cultivated plants and the same complexity and uncertainty gathers round the sources of the domesticated horses, sheep, oxen and pigs. With the exception of maize and barley, the cultivated plants are polyploids, *i.e.*, the number of chromosomes in the cells is a multiple of the diploid number which characterizes the normal species. This points to a probable hybrid source; but whatever the origin, the polyploidy provides material susceptible of the variation on which selection can work, even when it is not attended by giantism or an excess of vigour which would naturally draw the attention of the early cultivator. Though no wild species can be fixed upon as a starting point of our cereals, N. I Vavilov argued that the existing distribution of varieties points to certain centres as the original fountain of the cultivated races these being regions which are today characterized by a concentration of varieties in the cultivated fields, where a host of forms occur not yet segregated into distinct races and shade off into weed forms which equally inhabit the uncultivated land Vavilov thus indicated the highlands of southwestern Asia, particularly Afghanistan, as the probable centre of the soft and club wheats, northern Africa as the home of durum wheats, while einkorn, a primitive wheat cultivated in prehistoric times, may have had its origin in Asia Minor. Still another race, emmer, perhaps the most ancient of cereals, is found in patches all over the old world and only among isolated and backward peoples (*See* also AGRICULTURE PRIMITIVE)

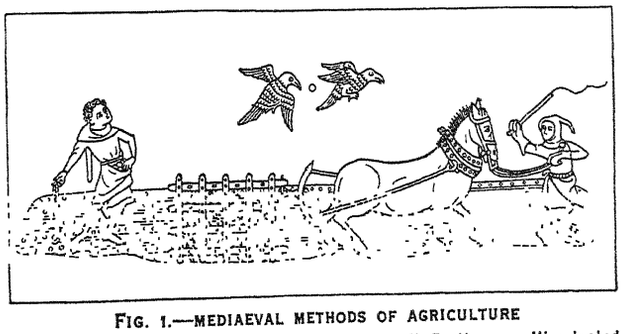

FIG. 1.—MEDIAEVAL METHODS OF AGRICULTURE

Similar general conclusions cannot be drawn concerning the early history of the growth of husbandry When agriculture appears in written history in the time of the Greeks and Romans (*see* GEOPONICI), it is already a highly developed art, which had behind it many centuries of empiric progress, the results of observation and of trial and error Cato, Varro, Virgil, Columella and the elder Pliny described an elaborate system of farming, embodying many sound principles, such as the value of leguminous crops as a preparation for wheat, for which modern science only lately found an explanation The methods of growing corn, vines and olives then prevailing were not substantially altered until the middle of the 19th century, and the sculptured representation of a sacrificial bull, lamb and boar on the *plutei* of Trajan in the Roman forum bears witness to an advanced state of stock breeding. Roman agriculture is indeed the foundation of modern farming, and though over a greater part of Europe it was disrupted by the barbarian invasions, its traditions probably never died out in favoured regions but were resumed in modern systems of farming

**Mediaeval Farming.**—The course of farming in England that prevailed in early days is in many respects common to all the invading northern peoples who drifted across Europe; it finds its parallels in all countries north of the Alps, in Russia and in India It is not uniform, since on the western side of Wales and Ireland, there is evidence of an earlier system, which is reflected in the grouping of the houses into scattered hamlets instead of into the larger villages characteristic of the more purely arable districts of the Midlands and eastern England. Whether the system was derived from an original communal ownership of the land and even of its produce is still a matter of dispute, but when records begin it had passed out of this stage and to some extent had been shaped by feudal theory (*see* ENGLISH HISTORY).

**The Manor.**—The unit of land holding and cultivation was the manor (*q v.*), of which there might be one or more within the parish. The land was held at one or more removes from the king by the lord of the manor, from whom the tenants held in return for various services and with varying degrees of freedom. The cultivated land lay in three, or some multiple of three, open arable fields, divided into strips of one or one-half acre, separated by baulks of rough grass and terminating in still wider baulks, the headlands on which the cumbrous ox team and plow could turn. On heavy land the strips were steeply ridged to throw off the water and this ridge and furrow still persist in many parts of the Midlands which have long been laid down to grass. In some places the old strips still defy cultivation, because of the labour that would be required to throw down the ridges and the infertility of the subsoil that would be bared in their crowns.

The three fields were cropped on a fixed rotation of winter grain (wheat or rye), spring grain (barley, oats, peas or beans, or mixed corn) and bare fallow. In each field the tenants held a certain number of scattered strips, the original intention being probably to give to every man a share of the good land and the bad, and mingled with them were the strips held by the lord and constituting his demesne. Each tenant farmed his own strips but was required to give a stated number of days' service to cultivate the demesne strips, services which gradually became commuted into payments in money or in kind. At a certain date after harvest the arable land was thrown open to the cattle to

wander over, and this of itself prevented any growth of fodder crops. On the lower land by the river would exist an area of meadow land to be laid up for hay and again divided in proportion with the arable land. The tenure of the particular strips for the year was often balloted for, a practice which still endures in places, as at Yarnton near Oxford. After hay harvest or Lammas the meadows were thrown open for common pasturage, hence the name "Lammas fields." Besides the arable and the meadows the manor embraced a certain amount of "waste," the origin of what today are known as "commons" (*q.v.*). On these the tenants had the right of pasturage and in suitable districts the right to cut turf or peat for fuel. They also provided fern for litter, reeds or heather for thatching, furze and brushwood for firing, rushes for the floors and other purposes, rough timber for fencing and building, stone, gravel and sand.

**Production.**—The farming that prevailed under these conditions was necessarily inefficient. Some manure appears to have been made by strewing roughage, marl or clay in the folds and in the "garsons," the little enclosures by the village into which the stock were driven at night; but the crops must have mainly depended upon the inherent fertility of the soil. The sheep were folded upon the fallow by night, though tenants were often obliged to put them upon the lord's land only. In the west where the area of unoccupied land was greater, there is evidence of a practice of moving the arable fields continually, whereby some fertility would be accumulated while the land lay in rough pasture Of extraneous fertilizers there were none; in areas on the chalk the practice of sinking pits into the chalk and spreading it on the land may have endured, for it is mentioned by Pliny in his account of Britain, and the traces of the old pits that remain in certain districts indicate a long continuance of the process of chalking and marling. The level of production was exceedingly low. Walter of Henley, who wrote early in the 13th century the standard treatise on the management of an estate, advised the sowing of two bushels of wheat per acre, which ought to yield threefold. From the context this would be a minimum, and the same author said that barley might yield eightfold, wheat fivefold, rye sevenfold, peas and beans sixfold and oats fourfold. Other sources justify placing the level of production of open field land in mediaeval times at yield of about ten bushels of wheat to the acre.

FIG. 2.—MEDIAEVAL HUSBANDRY Feeding chickens. From the Louterell Psalter, an illuminated ms. of the early 14th century. ("Vetusta Monumenta")

If the conditions of cropping were bad, the livestock were in a worse state. The stock of all the tenants and of the lord herded together and were driven afield and tended by the village cowherd, shepherd and swineherd respectively. The class of stock that prevailed depended to some extent upon the nature of the land. The open downs and heaths had many sheep, and the woodlands with their mast supplied feed for swine.

Pannage (*q.v.*) for so many hogs is a common entry in Domesday as an appanage of a particular holding. But with this mixture of everybody's stock little in the nature of selective breeding could be practised. Walter of Henley insisted on the value of good boars, but in general the bull and the boar were common to the manor—the result was a "haphazard union of nobody's son with everybody's daughter." Whatever disease came along ran riot through the whole herd or flock. Oxen were chiefly kept for work, and Walter of Henley considered an ox at work should consume half a sheaf of oats a day. Though the greater speed of the horse was recognized, it required more care, cost more to feed and was "carrion" instead of meat when worn out. Cows were kept for milk and the milk was mainly converted into butter and cheese. In the early summer they grazed on the "waste" and marshes or were tethered on the grass baulks; later they had the aftermath of the meadows and the stubbles. With the advent of winter the worn-out oxen and the old cows were killed off and salted down. During winter the cattle subsisted in the yards on hay, pea and bean haulm and straw. Rarely were cattle stall-fattened and the open field farmers sold most of their calves for slaughter. Sheep were from the earliest times an important element in English farming because of the value of their wool. The ewes were often milked, the toothless "crones" being killed for meat.

During the open weather they lived on the downs or the waste by day and were folded on the fallow by night; in the depth of winter they were housed or folded and fed upon whatever roughage was available. Swine afforded the chief meat of the community; they scavenged for a living in spring or summer and fattened upon the pannage of the woods. A few were specially fattened upon tail corn and the brewers' grains, for the barley that was grown was very largely turned into ale. The manor aimed at being self-supporting both for food and clothing. Rarely had even the lord any margin of corn for sale; the chief money revenue was derived from the livestock, wool, skins and dairy produce.

**Enclosures.**—The strict manorial system early began to break down. The lords often retained meadows and made enclosed fields which they either farmed themselves or let. Little holdings grew up by sufferance on the waste, occupied by "tradesmen" in the villages or other cottagers who also shared in the common grazing The rising value of wool in the late mediaeval times tempted lords to aim at enclosures of the arable, and recurring dearths and epidemics, of which the Black Death is the most notable, deprived the land of its labourers and facilitated the putting together of larger units of cultivation. From the earliest times the substantial independent farmer, represented by Chaucer's Franklyn, was a feature of English country life. Not only were the old feudal services commuted into rents, but by new intakes from the wastes or by fencing off portions of the open fields the tenants began to enjoy land in severalty. In Tudor times the process of enclosure was in full swing, though the legislature was opposed to, and public opinion was loud in denunciation of, a movement which appeared to diminish corn growing and the rural population. But the driving force was the growing commerce of the nation. Not only did both landlords and tenants want something to sell and look upon the land as the basis of a business rather than a subsistence, but the small holders who had been barely able to exist upon their little parcels of cultivation found other and more attractive outlets in the growing commerce and industries.

**The New Farming.**—It was toward the close of the Tudor times and in the early 17th century that the new farming began. Increasing intercourse with the continent and particularly with Flanders, where some of the old Roman tradition had persisted, brought new crops and stock and new methods into England Sir Richard Weston (1591–1652) who farmed in Surrey in Charles I's time, is credited with the introduction of turnips, clover and other sown grasses, and these crops providing winter keep were the foundation of the improved system of agriculture. With them cattle could be fattened and maintained during the winter; at the same time farmyard manure was made in quantity sufficient, with the help of the clover which enriches the soil in nitrogen, to raise enormously the whole level of production. The new farming could, however, only be practised on enclosed farms; on the open fields clover and turnips would be every man's property as soon as the common stock were turned on to them.

Turnips and clover were not the only introductions from the Low Countries; most of the common garden vegetables, as cabbages and cauliflowers, carrots and parsnips are owing to the same source. Fruit trees too were "fetched out of Flanders." Richard Harrys, fruiterer to King Henry VIII, bought "105 good acres in Teynham which he divided into 10 parcels, and brought plants beyond the seas and furnished the ground with them," which land "hath been the chief mother of all other orchards for these kindes of fruites." Hop growing also had a similar origin.

Doubtless the same thing happened with livestock, but here the evidence is more meagre because the descriptions of the early writers are so imperfect But it would seem probable that the large, long-woolled, white-faced sheep were originally of Roman origin and the Kents or Romney Marsh, the Lincolns and Leices-

ters, all on the eastern side of England, may well have been derived from a very similar sheep which is still found in Flanders. The importations may, indeed, have been earlier, for the English long wool was famous in mediaeval times and was among the first of the staple articles of export, its importance being still commemorated in the "woolsack" on which the Lord Chancellor sits. The earlier long wool chiefly came from the Cotswold country, the home of the other white-faced, long-woolled race of sheep, and this possibly may be a remainder from Roman occupation The black and white cattle which have always been about the eastern counties were certainly of Low Country origin—the modern Holstein-Friesian or Dutch cattle. It may even be surmised that white cattle of Roman origin (either directly or from the Rhine provinces) were progenitors of the Shorthorns, whose hybrid origin is betrayed by the mixed white and red colour of the roans.

**Enclosure Laws.**—The progress of enclosures grew apace in the 18th century. Whereas in early days it was opposed by parliament, in the 17th century it became possible to obtain sanction for agreements from the court of chancery, and from the time of Anne a strictly legal procedure by private act was made available (*see* COMMONS). Commissioners were appointed to make the award and apportion the several holdings to the tenants of the open arable fields, but a private act remained necessary until the General Enclosure Act of 1845.

Under the acts the commissioners could proceed to an award although a minority of the parties interested, one-eighth or even one-third, refused to agree. In certain counties—Suffolk, Sussex, Kent, Essex, Somerset, Devon and Cornwall, the marches of Wales, Cheshire, Lancashire and the four northern counties—enclosures were early and were but rarely effected by act. Possibly from the nature of the land the rigorous common field arable had never been usual in them. It was in the great corn growing areas of the Midlands, Yorkshire, Lincolnshire and Norfolk that so much enclosure by act took place in the 18th and early 19th centuries. After 1760 the process was much accelerated by the growth of industry and population even before the Napoleonic Wars created so great a call for good production. Valuable, indeed necessary, as enclosures were to the nation from the point of view of production, so great a change in the economy of the countryside could not be effected without much serious, if temporary, dislocation of labour and some permanent change for the worse in the condition of the poorer classes. Often the lord and the larger tenants took the opportunity of enclosure to put the land down to grass, so that a single shepherd would take the place of a dozen men who had formerly worked on the village land. The enclosures themselves may have been fair enough in their apportionments, though it would always have been easy for the lord and the bigger farmers to overweigh their poorer neighbours, but many cottagers who had no arable and therefore no title in the award found their customary rights of grazing swept away with the commons. There were those who held that the commons encouraged an idle race of casual labourers and poachers, but the other side of the picture, the destruction of a thrifty peasantry, was the theme of many writers in the 17th and 18th centuries.

Arthur Young, himself an unceasing advocate of enclosure, deplored the evils that had resulted therefrom. "By nineteen Enclosure Acts out of twenty, the poor are injured, in some grossly injured. . . . The poor in these parishes may say, and with truth, *Parliament may be tender of property; all I know is that I had a cow, and an Act of Parliament has taken it from me.*"

**The Agricultural Labourer.**—With enclosure began the creation in rural Britain of a race of landless men, dependent for employment upon the larger holders of land; and though the darkest days of this class did not come until the close of the 18th and the first third of the 19th centuries, when the pauperization caused by the old Poor Law became universal, the lot of the agricultural labourer, still the worst paid and worst housed section of the community, was established. Thomas Mozley wrote of his parish in Northamptonshire in 1829: "There were many farmers, several yeomen, very many small freeholders, as many tradesmen as the place could find work or customers for, and not one single labourer, in the sense of an independent workman offering his labour for wages, but a multitude of paupers."

The labourer class was also recruited from those yeomen proper who obtained small farms after enclosure but were unable to hold on to them. It required neither fraud nor force to displace the small proprietor; the mere pressure of economic change was sufficient A run of bad seasons, the constant temptation to mortgage, the inheritance by a widow, and the neighbouring proprietor who wanted to add land to land found his opportunity, especially where, as in England, land had for so long possessed a non-economic social value. Special opportunities were also offered to active men in industries and commerce, and since many of the old yeomen farms could produce but the barest living for their occupiers, they were sold and merged in larger holdings because the owners were no longer content with the income derivable from them In other countries peasant farming persisted largely because there were no alternative occupations with a higher standard of living within reach and because the layout of the land on the open

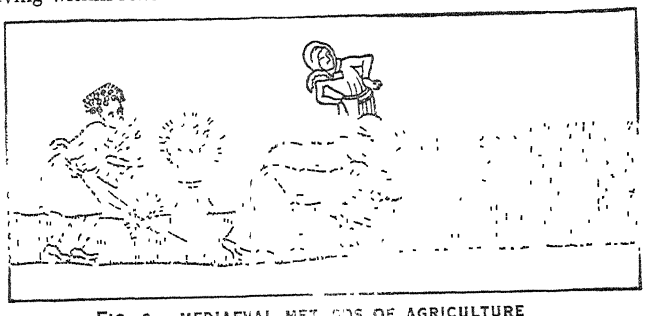

FIG. 3.—MEDIAEVAL METHODS OF AGRICULTURE
Reaping corn. From the Luttrell Psalter, an illuminated manuscript of the early part of the 14th century ("Vetusta Monumenta" vol. 6, pl. XXIII, fig. 3)

field system did not put an end to putting together large units of farming. The open field system nevertheless persisted into the 19th century; and even on the eve of World War II a nonenclosed parish farmed on the old English plan could be seen at Laxton in Northamptonshire and the parishes of Epworth and Haxey in the Isle of Axholme remained in strips, though the owners cropped them as they pleased.

**The Norfolk System.**—The improved methods of farming made possible by enclosure were soon manifest. Early in the 18th century what afterward came to be called the "Norfolk" or four-course rotation was being used. In consequence England became a grain exporting country during the first half of the 18th century, until the growth of population manifested itself with the development of industries. This epoch of British farming which became systematized in the early 18th century and endured until 1840, may be described as that of the conservation of the resources of the soil. The land was usually cultivated on a four-course system of two grain crops, alternating with turnips and a leguminous crop—clover or beans. The leguminous crop gathered nitrogen from the air and maintained the stock of this indispensable element of fertility at a comparatively constant level, despite the wastages that were going on. The turnips and the hay and straw provided for the making of farmyard manure, whereby there was returned to the soil the greater part of the valuable materials that the crops had taken out. Nothing left the farm except the nitrogen, phosphoric acid and potash sold away in the wheat and barley, the meat, milk and wool. Strict covenants prevented such wasting of the soil capital as would occur from the sale of hay or straw or roots, or the too frequent growth of salable grain crops. Under this system the average production became more than double that of the mediaeval farms Arthur Young spoke of 24 bushels of wheat as the average yield per acre; John Bennet Lawes, writing of Hertfordshire as he knew it when he began his experiments at Rothamsted about 1835, set the yield at 20 bushels, and the lower estimate is probably nearer the mark for the whole country. This level of production which may be compared with the six to ten bushels of mediaeval open field farming, could be maintained indefinitely. The limiting factor was generally the

supply of nitrogen, and this depended upon the recuperative actions of the leguminous crop in the rotation and of bacteria in the soil which made use of the organic matter supplied by the roots, the stubble and the straw, as against the removals in salable produce and the wastes that occur in the making of farmyard manure and in the soil itself under particular conditions, as leaching and waterlogging. The balance that was established was sufficient to maintain the yield at the level of 20 bushels of wheat per acre.

**Livestock and Other Improvements.**—Other improvements in agriculture were simultaneously in progress; great areas of waste land were being added to cultivation, especially on the heaths and light soils which before turnips and clover were introduced became immediately exhausted. Small's plow, the horse hoe, the drill, the threshing machine, were all inventions which took practical shape in the 18th century and did much to add to the effectiveness of the farming [illegible]. Drainage and the systematic amelioration of the land which had been impracticable on the open field system were taken up vigorously, though the wide extension of field drainage had to wait until the invention of drain tiles in the next century

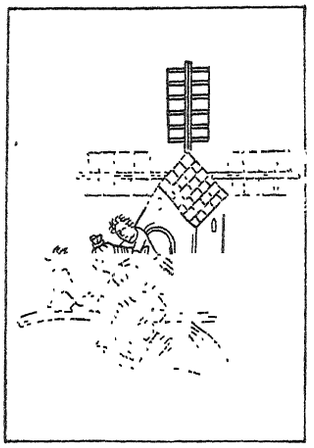

FIG 4.—MEDIAEVAL HUSBANDRY
Going to the mill. From the Louterell Psalter, an illuminated ms. of the early 14th century. ("Vetusta Monumenta")

Moreover, with the prevalence of enclosed fields, the improvement of livestock could be taken up with some prospect of rapid achievement. Robert Bakewell (*q.v.*) was the pioneer, and though he was unfortunate in selecting the Longhorn cattle to work upon, his creation of the Leicester breed of sheep persisted and led to rapid amelioration of all the long-woolled sheep. His methods were taken up by other men; Charles Colling made the Shorthorn breed, and John Ellman (1753–1832) the Southdown sheep which became the progenitor of all the other "down" breeds. England developed a race of breeders who combined the instincts of the fancier with certain definite principles. They began by selecting their breeding stock for conformity to an ideal type in which the meat was laid on in the most valuable places; by close line-breeding, even by inbreeding, the type was fixed and the "pedigree" sires became capable of stamping their own type in a few generations upon the common country-bred stock. Early maturity, the capacity to grow rapidly on good food, proved to be equally obtainable by selection, and the result was that in the 19th century Britain was possessed of a number of definite breeds of cattle, sheep and pigs that were doubly or trebly more efficient than were the old unimproved stocks. Their value may be gauged from the way the flocks and herds of the new countries of the world have been populated with stock of British origin. Shorthorns, Herefords and Devons are the great meat producers of the Americas, Australia and New Zealand; the only non-British breeds that achieved any world-wide extension were the Merino sheep because of their wool and adaptability to arid climates, and the Holstein-Friesian cattle because of their unrivalled milk yield.

**Capitalist Farming and the Great Landlords.**—The new agriculture which had grown up in response to the rapid increase of population under the beginnings of industrialism and had been overstimulated by the excessive prices that prevailed during the Napoleonic Wars, fell upon evil days with the break in prices and the restoration of a gold standard that followed the final peace in 1818. But it had accomplished its purpose of providing food for the nation from its own land, and it had completed the conversion of British agriculture from a system of peasant cultivation into one of capitalist business, small indeed in the main, but characterized by the employment of labour. In no other country did this development proceed so far. Prior to the disturbances arising out of World War I, most countries in Europe other than France, Switzerland and Belgium, could show vast estates farmed as single units and owned by the territorial nobility, but there was little or nothing of a middle farming class between the domain owners and the peasants, carrying on farming as a business on land rented from the large proprietor. In Great Britain the political, social and sporting privileges attaching to the possession of land early led to the building up of great estates, but the owner found the best use of his property in letting it again to tenants, who on their side took advantage of the opportunity for employing their limited capital in the business, by which they could derive a bigger income from it than if the greater portion were locked up in ownership of the land.

Thus in England the great landowners were the leaders of agriculture along its path of progress in the 18th century, even though most of the actual improvements, especially in stock breeding, were the work of tenant farmers like Bakewell, Colling and Ellman. A few large proprietors led the way and rendered better farming possible by their expenditures on reclamations and buildings.

They introduced the improved livestock to their tenants and they enforced sound methods of cropping by the covenants inserted in the conditions of tenancy. Prominent among them was the 2nd Viscount Townshend (*see* TOWNSHEND, CHARLES TOWNSHEND), Pope's "Turnip Townshend," who devoted himself to the improvement of his estate in Norfolk on a basis of turnip growing, with the use of the drill and the horse hoe. He is generally credited with the Norfolk four-course rotation, but it had been evolved before his time and he only gave to it a wider extension. The ideas that Townshend put into practice were chiefly derived from Jethro Tull (*q.v.*) of Berkshire, the greatest original thinker about farming processes that England had then produced. His *"Horse-Hoeing Husbandry,"* published in 1731, was the basis of all improvements in the operations of cultivation during the 18th and early 19th centuries. A little later Townshend's neighbour, "Coke of Norfolk," Earl of Leicester of Holkham (*see* LEICESTER OF HOLKHAM, THOMAS WILLIAM COKE) made a productive estate at Holkham of what had been little more than a rabbit warren, and became famous for his annual gatherings, the Holkham sheep shearings, where all the improving landlords and farmers of the day met and exchanged their experiences. There, too, the improved livestock of the time could be seen and judged. The duke of Bedford was equally active and held similar meetings at Woburn.

A little later the Earl of Egremont in Sussex, and in Scotland Hope of Rankeillor and Sir John Sinclair of Caithness, first president of the Board of Agriculture (1793–1822), may be singled out.

**Arthur Young.**—But the most active promulgator of the new methods was Arthur Young (*q.v.*). The younger son of a parson with a small property, Young began by farming, but with constant ill success. He soon found his proper *métier* in writing, and from 1767 to 1795 he published those vivid accounts of the farming and the men and manners of England, Ireland and France, which became classics of observation and shrewd judgment. In 1784 he began the publication of the "Annals of Agriculture," which embodied contributions from all the men of the time interested in agriculture, even the king himself. When a board of agriculture was established in 1793 Young became its secretary and was responsible for a series of county surveys of the state of farming in England which, if unequal and in some respects inferior to William Marshall's *General Survey of the Rural Economy of England,* remained the most trustworthy source of information. Young was pre-eminently a diffuser of knowledge; he had a sound knowledge of the general trend of agriculture, witness his unceasing advocacy of enclosures, and a quick eye for improvements of method. If his zeal sometimes outran his judgment in his commendation of innovations, his lively style always exacted interest and made him for 40 years a most effective stimulus toward the reform of farming. Rarely can a farmer be instructed in the method he is to follow, but he can be excited to think out a novel adaptation to his own conditions.

**Period of Scientific Progress.**—The accession of Victoria in 1837 marked the beginning of a new era in British farming. The occupiers of land had slowly adjusted themselves to the new conditions, after the shock caused by the break in prices at the end of the Napoleonic Wars. Confidence in agriculture was returning and a new race of landlords was growing up imbued with the idea that the scientific developments then in rapid progress could be applied to farming operations. In 1838 some of the leaders, among whom perhaps the most active was Philip Pusey, founded the Royal Agricultural society (*see* AGRICULTURAL SOCIETIES AND SHOWS), which gave a powerful stimulus to the improvement of stock, to experiments in cultivation and manuring, and to the introduction of machinery. Another small landowner, John Bennet Lawes (*q v.*) of Rothamsted, Herts., was beginning that fundamental series of field experiments which took formal shape in 1843 when he was joined by the young chemist, Joseph Henry Gilbert. At Rothamsted was laid the foundations of our knowledge of the use of fertilizers and the nutrition of animals. Previously there had been some empiric knowledge of the fertilizing value of such waste materials as woollen rags, soot and bones, but the supplies were limited and the employment only local. The first consignments of Peruvian guano and of nitrate of soda arrived in 1835; in 1843 Lawes began the manufacture of superphosphate, and his early experiments showed the value of the ammonia salts which could be made from the by-products of gas making, then becoming general. Other sources of phosphates than bones were rapidly discovered and about 1860 the great deposits of potash near Stassfurt, Germany, began to be exploited.

At the same time the science of agricultural chemistry was being explored and the theory of the nutrition of the plant—what it draws from the soil, the water and the air—a theory of which Justus von Liebig (*q v.*) had given a brilliant preliminary sketch in his British Association address, provided a rational basis for manuring. By 1850 the manufacture of artificial fertilizers was in full swing and though all too many farmers lagged behind in their application, their use, together with the employment of foreign feeding stuffs like linseed and cotton cake, the fertilizing ingredients of which found their way to the land through the manure made by their consumption, had by 1870 raised the general level of British production from 20 to 30 bu. of wheat per acre.

Other improvements influenced perhaps more the extension of the cultivated area than its increased yield. Field drainage was applied to great areas of heavy land under the influence of James Smith (1789–1850), of Deanston in Scotland, and of Josiah Parkes (1793–1871) whose demonstrations of the value of drainage became easy of application with Thomas Scragg's invention in 1845 of a machine for moulding cylindrical tiles. Smith drained shallow, 30 inches; Parkes put his drains in at 4 ft., and much of his work was in consequence wasted. Only after a great controversy between the two schools did it become clear that Smith's was the way to deal with ordinary heavy land which suffers because it cannot get rid of the rainfall, whereas Parkes' was the best method to cut off underground water rising from below. The improvements in cultivating machinery continued and in 1853 Crosskill put an efficient reaper at the farmers' service. The steam plow was designed and acquired a valuable if limited field of action. Pedigree stock made rapid progress; one by one the existing breeds of cattle, sheep and pigs became differentiated; breed societies and flock and herdbooks grew up. Improvements in crops also followed; Patrick Shirreff, John Chevallier, John Le Couteur and Frederic F. Hallet introduced the idea of "pedigree" into cereals.

From 1850 to 1874 farming was a prosperous business and money was poured into the land. British farming reached its high-water mark of technical excellence. It was reported that some farmers offered a reward to anyone who could find a weed on their cultivated land; no other country could show such yields of corn and roots; men came from all over the world to buy British livestock with which to improve their native races.

**Depression.**—All this prosperity culminated in the high prices occasioned by the Franco-German War; in 1874 a turn in the tide was manifest. A trade depression set in which limited the purchasing power of consumers; a run of bad seasons, culminating in the disastrous wet and cold year of 1879, brought ruin to many farmers. Other major causes beyond the control of farmers were at work to reduce prices. The growth of railways and the development of steamship traffic opened up the international trade in agricultural produce, and the wholesale settlement of new countries, particularly the western middle west of North America, gathered way. The area of the world devoted to wheat grew apace, faster even than the population; wheat prices fell year by year until 1894 The average *Gazette* price of English wheat was 54*s.* 3*d* for the decade 1865–74, 46*s.* in the next decade, and continued to fall to 22*s.* 10*d.* in 1894. During 1875–94, 124,000,000 ac of land were added to the cultivated area of the United States alone, and there were the corresponding increases in Canada, South America, Australia and New Zealand.

The other great factor was the appreciation of gold which began when Germany started to form a gold reserve after the war of 1870 and was accentuated by the falling yields from what had been the chief gold-producing centres of California and Australia. The situation was not rectified until the Transvaal became a big producer in the 1890s. The prices of all commodities fell, wheat more than the rest (according to Sauerbeck's index, all commodities fell 40%, wheat 51%), and some economists considered that to this cause alone was due the fall in agricultural prices and the resulting depression. But the vast increase of production must have also had its effect or the demand from the rapidly growing population would have counterbalanced it. During this period there was always a surplus of wheat and it was being grown at less than the cost of production, indeed it has been said that the only profit the pioneering American farmer made out of this situation was the eventual appreciation in value of the land he had settled.

Whatever the ultimate causes of the break in prices it had a disastrous effect upon British farming Neither farmers nor landlords realized how continuous the fall was going to be, or how completely indifferent would the price remain to the occurrence of a short crop at home; farmers could not readjust their methods and in many cases landowners did not reduce their rents in time to avoid a crash. Much of the old perfection of British farming had to go because of its expensiveness in labour, for during the whole of the period wages were tending to rise rather than to fall. Farm after farm was thrown upon the owners' hands; in Essex great areas of clay land became for a time derelict or were let to Scotsmen who would undertake to pay tithes and rates. In some cases the landowners had to farm themselves on an extensive scale; in others farmers who had acquired an art of cheap management had farm after farm thrust upon them until they were operating areas of 4,000 to 10,000 ac. These big businesses which grew up toward the close of the century were not reflected in the statistics, for the separate farms were still returned in the rate books as units. Indeed they were farmed as units, each with a bailiff but on the common system which the farmers had found to work; the buying and selling only were centralized. Though prices did turn slightly after 1895 it was not until the close of the century that the conditions began to appear at all stabilized. By that time men had learned to cheapen their methods in the purely arable districts and in others the growing demand for milk had afforded an outlet. The Essex clay lands came back into use, if not under the plow, with a new race of Scotch and Devonshire milk producers. Prices of meat and wool had fallen though not to the same extent as with cereals, and the distress in the west and north of England had never been so great as in the purely arable counties. In some districts special crops solved the farmers' difficulties; a great potato industry developed in the Fen country, where energetic men with intensive methods built up large holdings out of the bankrupt small farms; but the price of potatoes, like that of milk, was made at home, foreign competition being negligible there, while the demand grew with a larger and more prosperous population. The growth of vegetables, fruit and flowers also provided an expanding industry, and the demand for such things increased with the rise in the standard of living.

**Loss of Arable Land**—But such commodities provided the exceptions; in the main the farming community had to meet the depression by reducing expenditure, despite the resulting fall in production. The acreage only under wheat in England, 3,337,000 in 1872, had shrunk to 1,745,000 in 1900; yet there was no accompanying increase in the yield per acre such as should have attended the abandonment of the poorer land, without taking into consideration the improvements in the varieties grown and in the supply of fertilizers. The chief resort of the English farmer in order to meet the situation was to lay his land away to grass. Thereby he shifted his production toward the more remunerative livestock and at the same time reduced the labour bill, because on grassland one man may suffice for 200 or 300 ac., whereas on the arable land about four men per 100 ac. were then employed. Only when dairying on grassland, was a staff required comparable with that employed on the plowland. Between 1872 and 1900 the area of land under the plow in England was reduced by more than 2,500,000 ac., or nearly 20% of the amount in 1872. There were some notorious examples of these changes; in one case on the Berkshire Downs some 4,000 ac. of plowland were converted into a sheep ranch tenanted only by a few shepherds, the old farmhouses and hamlets perishing away in desolation. In England and Wales the agricultural population diminished between 1871 and 1901 from 1,269,371 to 951,674, or nearly one-quarter. In Scotland the reduction in arable land was not appreciable, but a similar saving was effected by lengthening the duration of the leys in the rotation; the four-course shift became a five- or a six-course, with two or three years of temporary grass instead of one. (*See* ARABLE.)

For all the reduction of cultivation and the lower standard of farming the period was not entirely one of retrogression. Improvements in the quality of livestock, especially in the direction of early maturity, in the production of milk, and in the special branches of potato growing, market gardening and fruit growing continued. The self-acting reaper and binder began to be imported in 1873 and proved the great labour-saving implement of the period, though at the outset it only intensified the pressure of competition, since it was worth more to the wheat grower in new countries short of labour than it was to the British farmer. This distressed state of agriculture became the subject of more than one royal commission and parliamentary inquiry, none of which, with protection ruled out as contrary to national policy, could suggest any substantial alleviation. The one legislative action of importance was the creation of the Board of Agriculture in 1889. This action recognized the importance of agriculture in the national economy, since no other industry had a special department in the government. The new board took over certain existing services such as the collection of statistics, the control of scheduled animal diseases, and the administration of tithes, enclosures, and university and college estates and was charged with one new function, the allocation of £5,000 a year for the assistance of agricultural and dairy schools.

**Agricultural Instruction.**—The first systematic attempt at agricultural education began about 1890, and in its train followed some new beginnings in research. The great start made at Rothamsted had been left solitary and unaided, though other countries were copying its methods and extending them into all the sciences which bear on agriculture. The movement was too young to have any effect on the industry before the close of the century; it had to overcome the intellectual inertia of a class which had always been indifferently educated and had no opinion of book farming, while the new scientific teachers had to learn what was good in the practical man's outfit and to recover from their own mistakes. One new fertilizer had been added to the list available for the farmer, namely, basic slag, a phosphatic by-product of the steel industry which was to do much to improve the growing area of grassland But owing to his poverty the British farmer was not using fertilizers as much as he might have done, and the greater part of the British production of sulphate of ammonia was being exported.

Steady recovery and quiet progress under the favouring wind of slowly rising prices characterized the opening years of the 20th century. Knowledge was growing, both from the example of successful practitioners and from the technical instruction that was becoming more generally diffused. Statistically the industry continued to decline; the arable land of England diminished by a further 1,000,000 acres between 1900 and 1914; nor was there any compensating increase in the numbers of livestock, though the output was improving as better methods of feeding and breeding brought the animals earlier to market. All over the country examples could be found of progressive and prosperous farmers who were taking advantage of the resources science was increasingly putting at their disposal. But many were still set in old ways; mindful of the bad times that were not far off they sought the path of safety first and were distrustful of all enterprise that might cost money. In the use of lime, fertilizers and other ameliorations of the soil the farmers were falling behind their competitors in the Netherlands, Denmark and Germany, just as in the applications of machinery they could not rival the farmers of the U S. and Australia. Labour was still too cheap in the agricultural counties of England; farmers still clung to the traditions that had answered when wages were 7*s.* a week and wheat over 6*s.* a bushel.

**Marketing.**—Above all the weakness of British agriculture as an economic unit was being exposed. The rapidly growing population was to an increasing extent being fed from overseas; in the five years preceding 1914 the United Kingdom only produced 42% of the food it consumed as measured in calories, including only 20% of the wheat it needed. Great Britain was the one open market for the agricultural surpluses of the whole world, for the one or two small countries that also persevered in a free trade policy were themselves exporters of agricultural produce. In consequence great commercial interests grew up to exploit this import trade, interests that could impose upon the aspirants for a place in the British market those conditions of uniformity of produce, standardization of output, and attractiveness of packing, which made for ready sale. Because of their dependence upon an export trade competitors were marshalled into co-operative societies, and through this discipline the peasant farmers of other countries secured all the advantages of marketing which might have been expected to belong only to the big businesses. The typical British farmer, who in his day had been a nonefficient unit for the sale of his staple produce and could look down upon the exploitation of the peasant was loath to forgo his individuality and slow to [illegible] weakness in the world's markets. The lack of leadership and organization was all a part of the want of public confidence in an industry which had become somewhat remote from modern life. The great landowners no longer regarded agriculture as a money-making business; they maintained home farms because of the traditional association of the English gentleman with the countryside and because the exhibition of pedigree stock was a recognized form of social competition; but the lawyers, the bankers and the capitalists remembered the past and had no belief in the earning capacity of the land. No joint stock enterprise to produce food at home could hope to obtain public support, however much money might be forthcoming to exploit wheat or wool, tea or rubber or copra abroad. The farmers who were making money said little about it and trusted to obtain whatever capital was needed for their businesses, many of them extensive, from their friends or trade connections. Politically the farming interest did not count; in parliament there could be no agrarian party, hardly even an agrarian member, because even in a purely rural constituency the more numerous labourers were not likely to vote with the farmers. Nor was there any policy upon which the agriculturists were united; although most farmers were still protectionists, such a measure was taboo to all parties so far as concerns food and even with the agricultural labourer the dread of higher prices outweighed the hope of better employment.

The one political measure of outstanding importance was the Small Holdings Act of 1908 which empowered county councils to acquire land and equip it for small holdings and allotments (*see* ALLOTMENTS and SMALL HOLDINGS). This act was a sign of growing public interest in agriculture and a feeling among thinking people that the urbanization of Great Britain was proceeding too fast and that some measures should be sought to check the drift of men away from the land. The triumphal march of industrial-

ism from factory to factory had lost some of its attractiveness; statesmen no longer regarded the simple theory of Great Britain wholly given up to manufacturing and exchanging its goods for food, as desirable or even safe. So the Small Holdings act was an attempt to recreate the peasantry that had long been dying out in Britain, and to provide access to the land for men whom circumstances had driven into the towns but who still felt a call to the soil. The growth of small holdings could do little toward reducing the volume of imports; the impulse was social rather than economic, but a small holding might give the energetic man a start toward a larger farm. The statutory small holders rarely failed to establish themselves, but their numbers barely sufficed to keep pace with the wastage that was elsewhere going on (*see* SMALL HOLDINGS).

**The Development Fund.**—Another measure of perhaps more far-reaching consequences was Lloyd George's Development Act of 1909, by which was set up a commission endowed with ample funds, the function of which was to promote research and education in agriculture and to carry out other experimental work in rural industries which might help to restore prosperity to the countryside Thanks to this fund British agriculture began to be provided with an adequate establishment for research and investigation, such as the United States, Germany and other progressive countries already enjoyed. Some results from research were already accruing The plant breeder's improvements were quickly recognized by farmers, and Rowland Biffen of the Cambridge School of Agriculture and E. S. Beaven of Warminster, working independently, had applied Mendelian principles to the breeding of new varieties of cereals. Some of Biffen's wheats and Beaven's barleys were already being widely grown by farmers in the progressive districts and their success did more than anything else to convert farmers to a belief in the value of research.

Toward the close of the period the tractor plow, driven by an internal combustion engine, began to appear. It could be operated on a farm of ordinary British size, whereas the steam plow was only economic on an extraordinary acreage and had become an emergency implement only hired for special work. Imperfect as the motor implement was, it offered potentialities of speeding up and economizing manual labour which have not as yet been fully realized.

**World War I.**—War halted these forces of quiet progress. Its first effect was to sweep the agricultural colleges and research institutes of their students and younger staff members for military service. For the first two years of the war the farmers were told to carry on their work as usual. Prices rose steadily but not abnormally, though here and there special shortages developed. It was not until the submarine campaign became ominous in 1916 and harvests at home and in the U.S. were deficient that the government deemed a special agricultural program vital.

Early in 1917 the Board of Agriculture under the presidency of Rowland E. Prothero (later Lord Ernle) set up a Food Production department directed by Sir Arthur Lee (later Lord Lee of Fareham), and county committees with power to direct the crops to be grown were constituted. Little could be done to enlarge the area under crop in 1917, but each county was assigned an area of land to be put under the plow for corn and potatoes. Attention was also given to land inadequately cultivated. Services were organized to provide and distribute steam and tractor plows, horses and implements. Labour was recruited from every possible source, including interned persons and prisoners of war. Many women helped, training centres being set up to make them and other unskilled labour serviceable. The supplies of seeds, fertilizers, feedstuffs and other necessities like binder twine were organized, and the necessary transport and credits for purchases overseas were arranged. Although late, the program was prosecuted with great vigour, and even in 1917 the area devoted to wheat, barley, oats and potatoes was considerably increased. The cultivation in allotments of all spare ground near cities and towns was promoted. This movement (*see* ALLOTMENTS) was of no small value in mitigating later food shortages.

To meet the emergency and also provide a permanent policy of encouraging agriculture for the national welfare, the Corn Production act was passed in 1917. It guaranteed certain prices for cereals, but the rapid rise of prices rendered the provisions unnecessary during the war. It also provided for wage boards to determine minimum wages for agricultural labour from year to year in each district, but the price situation developed so rapidly that the boards fixed the actual rather than the minimum rates Landowners were debarred from raising rents in so far as such increases could be ascribed to the guaranteed prices. The act sought to maintain and extend the area of cultivation, and regardless of its defects it was the first coherent scheme that recognized the needs of all classes interested in the land.

The course of prices was of more immediate interest to the farmers. Early in 1917 shortages attended by rapid rises of prices and speculation among dealers forced the newly formed ministry of food to fix prices and then ration all major articles of food These steps involved a very complete control of all phases of distribution; prices had to be fixed for both the producer and the consumer, the middleman's allowances were determined, and the supplies had to be allocated to the needs of each district. The food controller had to compromise between the high prices necessary to stimulate production and the low prices required by the consumer. The consumption of bread was left uncontrolled, but its price was kept down by a subsidy. It was also necessary to fix the prices on much of what the farmers produced on a reasonable parity so that they would not be tempted to concentrate on the production of the most profitable. A shortage in cattle food developed since the rationed ships' tonnage for goods from overseas had to be reserved for essential human foodstuffs, soldiers and munitions. The normal home production of cattle food was likewise reduced because wheat was milled more deeply and this produced only 5% or 6% offals as compared with 30% before the war. Actually the milk herd of the country was not appreciably reduced, but the sheep population declined by 1,500,000 between 1916 and 1918, and the pig herd declined from nearly 2,500,000 in 1914 to 1,700,000 in 1918.

During the latter part of 1917 and early 1918 the program of the Food Production department and its county committees found a real response. In 1918 as compared with 1916 the total arable land of the United Kingdom was increased by 1,720,000 acres and the land under crops by nearly 3,000,000 acres, the increase in wheat being 750 000 acres, in oats over 1,500,000 acres, and in potatoes nearly 400.000 acres. But the withdrawal of more men for military service in the spring of 1918 and the disastrous harvest conditions so intensified the opposition to compulsory plowing that no further progress was made. In fact the acreage in grain in 1919 was nearly 500,000 less than in the preceding year. With the end of the fighting in Nov. 1918, the farmers turned very strongly against control, despite the persistence of the crisis of food supplies

**Effect of World War I on Farming.**—The consequence of the war conditions which persisted until near the end of 1920, when the food controller's operations were relaxed, was a great temporary prosperity for the farmers. Although they had to sell their wheat at less than the world price and the cost of labour and supplies rose to a high level, rents did not vary and the balance was strongly in their favour. They also enjoyed the benefit which affects all farming operations, namely that on a rising market some of the costs, particularly labour, are incurred on a lower scale than that of the realization. While the largest sums of money were realized from potatoes and vegetables, probably the highest rate of profit was on the grazing farms which sold sheep and wool, young stock and milk, and employed little labour. But the only men who really kept their profits were those who gave up their farms and sold their stock before the end of 1920.

The most immediate effect of these farming profits was a sharp rise in land values. During 1918–21 there were immense sales of agricultural land amounting on a conservative estimate to 3,000,000 ac. in England and Wales. About one-eighth of the farming area of the country changed hands in these years at greatly enhanced values. Landowners were not able to raise rents though their disbursements for tithe, repairs and taxation had increased, farms being in demand, they could treble or even quadruple their

net incomes from land by selling it and investing the proceeds in government stocks. Tenants were anxious to retain their holdings but had to buy in order to do so.

Consequently these years saw the creation on a fairly large scale of an owner-occupier class of farmer. Some of these men had already made money enough to pay for their farms or were able to do so while prices were high; they were comparatively safe when the crash in values came in 1921. The men who then found themselves in difficulties were those who had bought their farms on borrowed money and still carried the mortgage; still more those who had entered and stocked their farms in the period of high prices.

Considering the production of the country the advance in the arable and particularly in the grain area attained in 1918 was not maintained even in the years of high prices that persisted until 1921. All powers of dictating cultivation were abandoned at the close of the war As regards livestock the size of the milk herd was maintained, though the beef herd suffered a small decline. The sheep flock of Great Britain, of England in particular, was greatly diminished; in England and Wales it stood at about 17,500,000 at the beginning of the war, had fallen to 16,500,000 in 1918 and reached its lowest point, 13,383,000 head in 1921, while analysis of the returns shows that the loss had fallen almost entirely upon the sheep of the arable counties. Arable sheep farming had always been a special British feature characteristic of the open country upon the chalk and the sands. There half the arable land used to be farmed with fodder crops—rye, winter barley, tares, rape, kale, turnips and swedes, which were sown so as to afford a succession of green crops upon which the sheep were closely penned in folds that were moved day by day on to fresh ground.

In addition to their green food the sheep and lambs received a little hay and corn and cake to force them on for market at an early stage; the land received the benefit of the manure made from the food and the treading of the sheep. This system, the sheet anchor of the older light land farming, was unsuited to war and postwar conditions. The labour required, both for the fold and the growing of fodder crops, was too expensive at the new wage rates, the supplementary feeding stuffs were unobtainable, and prices tempted the farmer to sell all his flock and put the land into grain. Again fixed prices ignored quality; the arable sheep farmer could no longer realize the extra price he had been accustomed to obtain for his quickly-grown lambs. Consequently the great arable sheep areas in Hants, Wilts and similar counties lost up to 50% of their sheep and though their numbers revived later the restocking was with grass breeds like the Cheviot-Border, Leicester half-breeds, Exmoors, Kerry Hills, etc., to the permanent loss of the Down breeds, like Hampshires, Oxford Downs and Southdowns.

The stock of pigs suffered great reductions with the shortage of feeding stuffs in 1917, 1918 and 1919. The herd which in England and Wales had remained for many years at about 2,000,000 fell to 1,700,000 in 1918, but recovered rapidly to more than its previous level, reaching 3,250,000 in 1923. The numbers of poultry followed much the same course as that of pigs and from the same causes, but the postwar development was more marked with the rapid extension of the knowledge of skilled poultry management.

**Depression of the 1920s.**—War prices were maintained until the spring of 1921; then they dropped by about one-third by the close of the year The prime cause was the deflation of money in Great Britain and the U.S. which was then effected; the secondary causes were the abundant harvests in the vastly expanded area of cereals in the Americas, particularly in Canada, and the lack of purchasing power among the war-ruined population of Europe. Prices in Britain continued to fall until 1923, then tended to recover a little until the long-continued coal strike of 1926 produced a new fall which specially hit the class of farmers who had so far suffered least namely, the producers of milk and meat. The situation was aggravated by a succession of bad seasons after 1918, which of themselves would have hurt the position of farmers even in normal times. Bad growing seasons, wet harvests and foot and mouth disease, were serious contributory factors in the ruinous condition in which British farming found itself. Deflation alone wrote off nearly half the capital farmers estimated they possessed in 1921, and though this did not really alter the position of men who had been farming continuously from before the war, it fell heavily upon those who had entered farming during the years of high prices or had mortgages out from the purchase of their farms.

**Postwar Legislation.**—The state of agriculture was not without consideration and legislative action during the period after World War I. War experiences persuaded both parliament and the general public that the maintenance of a prosperous agriculture was of some moment in the national policy. Even during the war a reconstruction committee under Lord Selborne had examined the question and drawn up a series of recommendations on which the Corn Production Act of 1917 had to some extent been based. But that act, as already seen, had immediately become nugatory as far as guarantee of prices was concerned. As the outcome of a royal commission in 1919 an Agriculture act was passed in 1920, which accepted the main principles of the old act by charging the state with the payment of subsidies on the acreage of wheat and oats grown, whenever the prices fell below the assessed costs of production. The county agricultural committees became statutory bodies endowed with powers to determine tenancies in case of persistent bad cultivation or neglect, and even to enter upon the land and act themselves in cases of default Wages boards were continued and tenants were given greater security of tenure by provisions which compelled the landlord to give compensation for disturbance equivalent to a year's or even up to four years' rent, unless the county agricultural committee would certify that the notice to quit was justified by the bad cultivation of the tenant. The Agriculture act had, however, but a brief existence. It antedated by only a few months the break in prices of 1921, and it soon became evident that under the guarantees the state would be called upon to pay a very large sum upon the acreage of wheat and oats grown. The basal figure had in fact been set much too high for oats, a crop which is mostly consumed upon the farm and which therefore does not greatly affect the income of the farmer. But no attempt was made to remedy this defect; the public cry for economy was so insistent that the act itself was repealed in 1921 within ten months of its passing, in spite of all the promises set out in the act that four years' notice would be given before the guarantees were withdrawn. The repeal coincided with the very situation the act was designed to obviate, a wholesale break in prices brought about by causes beyond the control of the farmer, and in this case by the deliberate deflation policy of the government. With the guarantees the wages boards disappeared and though conciliation committees were set up in most counties, the average weekly wage dropped from 42*s.* in Sept. 1921, to less than 28*s.* before the end of 1922. The repeal of the Agriculture act put an end to all ideas for a national constructive policy for agriculture and the industry was left to sink or swim by its own powers and be guided by its own lights. The action was part of the pessimism of the time, of the war weariness that shirks any sustained effort and doubts the value of any planning for the future. Bitterly as it was resented by the farmers, who thereby lost all confidence not only in governments but in agriculture itself, it was angrily acquiesced in, because they got rid of their two greatest bugbears—the shadow of control of farming and wages boards. The resentment generated by plowing-up orders given in 1918 and other interferences consequent upon the orders of the food controller, had been worked up to an intensity out of all proportion to the actual hardship that had been inflicted, and farmers generally were prepared to purchase freedom at any cost. A very large proportion of them indeed grew little wheat or oats and were anxious to grow less in the difficult state of arable farming. So the farmers' representatives, while protesting, accepted the situation; they saved those sections of the act that gave them compensation from disturbance (provisions which injured the landowners and were in many respects a hindrance to the improvement of farming) and they obtained as a slight recognition of the sacrifice imposed upon them the allocation of £1,000,000 to the extension of agri-

cultural research and education.

After the war the National Farmers' union, in which was concentrated the political opinion of the farming community, objected to any further interference of the state with agriculture. The distressed state of the industry gave rise to a further inquiry in 1923—the Agricultural tribunal, consisting of three economists not directly connected with agriculture, who produced an illuminating survey of the subject early in 1924. Its main recommendation, a subsidy upon arable land with further assistance to the growth of wheat, received little support from the farmers' organizations and was never adopted by the government of the day. It also recommended the re-establishment of the wages boards and this was effected in 1924. An act in 1922 disposed of a long-standing controversy by permitting the admission of Canadian store cattle into Great Britain, and the Agricultural Credit act of 1923 gave some relief in the shape of cheap mortgages to farmers who had purchased their holdings during the operation of the Corn Production and Agriculture acts. The British Sugar (Subsidy) act of 1925 provided a very ample scale of subsidies on sugar produced in Great Britain, for a period of ten years, in order to encourage the establishment of a sugar-beet industry in the country.

**Wages and Prices.**—The low agricultural prices of the 1920s and 1930s were not due to overproduction, since as far as can be estimated the gross output from the land of the world, actually lower in some items, did not keep pace with the growth of population after 1914 (*see* below, *World Agriculture*). That this shortage did not result in higher prices was due to the destruction of the purchasing power of so many of the countries of the world, through war and revolution and the depression in industries. The efforts that so many states made toward a deflation of their currency was regarded by many economists as the immediately operative factor, depressing prices for all producers and destroying the confidence upon which industrial activity depends.

The other element in the equation—the relatively high cost of labour—could not be met in England by a reduction in the wage rate, which in agriculture was already below that prevailing in other industries. Indeed, bad as was the state of trade, men left farming for other occupations; many farmers complained of the shortage of labour, and in certain cases where profits were assured, as in sugar-beet growing, labour from Ireland was imported. Any local call for men immediately drew agricultural labourers from their following and when any general revival of industry took place the land was likely to lose most of its active and able-bodied men. Thus if no other change supervened, farming, except for those special businesses that could command a sheltered or a luxury market, was reduced to a species of ranching with a minimum of labour. There was one alternative—a sustained effort to make labour more effective, on the one hand by better organization, by the use of machinery and the elimination of wasted effort, and on the other by careful training to increase the skill of the individual. Much of what was called "good" farming before World War I was still dealing with labour on a mid-19th century basis of wages, and though operations had been cheapened after the fall of prices of the '80s and the '90s, there had been no radical reconsideration of methods such as was called for by the modern relation of wages to the prices of agricultural produce. This was the big problem before British agriculture—the revision of all its traditions of husbandry, and it required the co-operation of the investigators, both scientific and economic, with the study by individual farmers of the conditions imposed by their own farm and particular business. The investigators might supply stimulus and guidance, but the main effort would have to be exerted by the farmers themselves, for the problem was one of management and practice, demanding a consideration of the technique of farming and the arts of leadership and management that had not been forthcoming for the last two generations. Some encouragement and renewal of confidence could come from increasing prices, for the withdrawal of men from the land because of the superior rewards in other occupations was not confined to Great Britain but was common to all countries. It affected the peasant as well as the wage-earning labourer; it was manifest in the United States as in France.

**Agricultural Co-operation.**—The obviously attractive advantages which can be obtained by buying and selling on a wholesale scale and the great success attending co-operative effort among farmers abroad, particularly in Denmark, caused agricultural co-operation (*q.v.*) to be pressed upon the British farmer for many years. The work of propaganda and advice was undertaken by the Agricultural Organization society, which was modelled on the successful Irish society initiated by Sir Horace Plunkett The A.O.S. was a voluntary organization supported by subscriptions from its affiliated societies, but it enjoyed a considerable amount of subvention from the Development fund from 1910 to its demise in 1924. The earlier efforts at co-operation chiefly aimed at the formation of purchase societies to supply the farmers' requirements for fertilizers feeding stuffs and other materials. Though many of these ventures had but a brief existence some became strong trading corporations, such as the Eastern Counties Farmers' Co-operative society at Ipswich. A wholesale society, launched during World War I with the object of bulking the purchases of individual societies, came to disaster. Little progress was made with societies for the sale of farmers' produce, though a number of [illegible] depots flourished. Dairy societies had a somewhat [illegible] existence; in some cases as soon as they attained local success they attracted the attention of one of the big dairy firms and after a period of fierce competition either succumbed or were brought out. Eventually the Agricultural Organization society, despite all the devoted work given to it and the subventions it had enjoyed, found it necessary to dissolve. It had never received any wide measure of support from farmers, and as the National Farmers' union had become the representative organization of the farmers of England and Wales and was prepared to take over the care of co-operative action among its members, the old society gave way to the National Farmers' union. At the same time the government under the Agricultural Credits act made provision for loans to Agricultural Co-operative societies on the basis of a loan of 20*s.* for each 20*s.* share taken up by members, of which no more than 5*s.* need be initially called up. The history of these latter ventures was not altogether encouraging. At the same time there was a movement for the setting up of co-operative bacon factories on Scandinavian models. Seven such societies were started. Two active wool-selling agencies were established, one in the southeast and one in the northern counties, both of which steadily progressed. In 1925 on the termination of the wartime hop control, a voluntary organization to continue the collective sale of hops succeeded in enlisting some 90% of the hop growers of the country. While other examples could also be named, speaking generally, agricultural co-operation made but little progress among the farmers of England.

The reasons are not far to seek. In the first place the larger English farmers make their purchases on a big enough scale to secure terms comparable with those offered by the co-operative society. When such men joined a purchasing society they were apt to use it merely to beat down the terms offered by their merchants. The smaller farmers followed the lead of the big men or were unable to forgo the credit they obtained from the merchants. Again the firms dealing in agricultural necessaries were very firmly entrenched in Great Britain; many of them were bigger and more efficient than a newly-started co-operative society could be, and having capital behind them did not shrink from competition They had the great advantage too of being able to offer credit, and their agents being generally drawn from the farmer class had friends and connections among the men with whom they wanted to do business.

Societies for the sale of farmers' produce had an even more difficult task. Trade rivalry was equally strong; the customary markets were close at hand and farmers were loath to forgo their individuality or renounce the chance of a temporary rise of prices. Co-operative selling involved working to contract and the production and regular delivery of a standardized article. The bacon factories failed largely because they could not ensure a regular supply, the farmers diverting their pigs to other channels when

prices rose. Firm contracts to deliver regularly were refused by the producers or could not be enforced. Milk societies were compelled by their members to give a price too high for successful working because a competing trader with a long view would offer prices above the economic parity. Certain ventures failed also from embarking upon a manufacturing process, like bacon curing, which requires a considerable degree of technical skill, and the inability of the society to pay a competent manager or else to find one before its resources went.

The existence of a near-by market is the great obstacle to agricultural co-operation for the sale of produce. Nearly all the examples that are so freely quoted of the success of farmers' organizations—the bacon factories of Denmark or the fruit-selling associations of California—rest upon the fact that only an export trade is available and that farmers cannot engage individually in such a trade. They are driven to organize because the alternative is the control of a wholesale trader who cuts the producers' returns to the minimum that will keep them in business. For these and other reasons the true co-operative spirit was lacking, and British farmers did not show that loyalty to the principle of combination which would induce members to stick to their society even at the cost of some loss to themselves. When there is an old-established market at hand it is almost impossible for a co-operative business to give the farmer better returns at once. Psychologically, too, defaulters and men who stand outside a combine have a powerful disintegrating influence upon it. They share in all the benefits if the combine succeeds in raising the general level of price; they take no risks and get paid at once, while members may be waiting for a portion of their returns because the society has only succeeded in raising prices by withholding part of the crop from the market. The "outsiders" would not be human if they did not boast about their advantages, and English farmers were as yet too easy-going and too much merged in the general community to counter with a social boycott. Similar occurrences in certain of the British dominions resulted in legislation to force recalcitrants into any combination which secured the adhesion of three-quarters or four-fifths of the producers; but such procedure was quite alien to the English farmers' declared policy of "no control." Yet the acceptance of voluntary control is the essence of co-operative organization, and by virtually compelling farmers to produce the article wanted by the market, rather than that which they fancied, exerted a powerful educational influence. On the other hand if he did not accept the voluntary control of his own organizations the British farmer was likely to drift into subjection to the much less sympathetic control of big businesses which would make of him a tied producer.

Thus the prospects of agricultural co-operation did not appear bright, though the situation was not without hope; a sense of the necessity for combination was growing. Nothing could be gained by preaching co-operation at large, but little by little particular instances were making good, especially where the association only attempted to sell and not to manufacture the raw material provided by the farmer. An alliance might be possible with the great co-operative organizations among consumers, which indeed had hitherto been spending their efforts in organizing foreign rather than home producers. But it was only by combination of some sort, from within or from without, that British farmers could hope to retain a remunerative share of the best of all agricultural markets—that of Great Britain. (*See* AGRICULTURAL CO-OPERATION.)

**British Farming Systems.**—British farming is characteristically an affair of small capitalist businesses employing paid labour. Characteristically, too, the farms are tenancies held under yearly agreements, though the tenant is largely protected from disturbance by the Agricultural act The landowner provides the permanent equipment of the farm buildings, gates and fencing, water supply, drainage. The landowner also is responsible for repairs to the fabric, but minor improvements of which he will remain possessed are generally carried out on the basis of the landowner finding materials—timber for fencing, bricks, stone, gates, drain tiles, seeds for permanent pasture, etc., and the tenant finding the labour. The landowner's capital has been estimated to amount on the average to £31 per acre, the tenants to £12–£15 per acre, and the average rent to 31*s.* per acre. Under such a system the entry upon and leaving of a farm, at whatever date, necessitates a considerable adjustment of account between landlord and tenant, since the farm must be left as a going concern. These adjustments were formerly regulated entirely by custom and though they were now governed by the various Agricultural Holdings acts (consolidated in 1923), custom was recognized and still played a large part. The basis of the act was that the outgoing tenant was entitled to compensation from the landowner for all improvements he has effected, the amount of compensation being determined by the value of the improvement to the incoming tenant. For certain types of permanent improvement, *e.g.*, buildings, fruit trees, etc, the tenant was not entitled to compensation unless the consent of the landlord had previously been obtained. The purpose of this exclusion was to prevent the tenant from committing the landowner to payment for an improvement which the latter might not be able to realize. For example the improvement effected by planting land with fruit or hops might be valued as high as £100 an acre, with embarrassment to the landowner if he had to pay out this sum on the determination of the tenancy without any assurance of being able to find a tenant willing to pay an adequate rent for it. An exception was made in the case of holdings let as market gardens. Here general legislative sanction was given to what was known as the "Evesham custom." The tenant possessed the right of free sale of the improvements he had made, *e.g.*, beds of asparagus, fruit plantations, etc., but had to find the purchaser, the landowner being obliged to accept the tenant proposed by the outgoing tenant, who had made his own bargain for the improvement with the new tenant.

In ordinary cases the negotiations with regard to improvements proceeded between the outgoing and the incoming tenant, in whose agreement with the landowner was a clause that he should pay whatever compensation was due to the outgoer. Each tenant appointed a valuer who between them prepared an agreed valuation of the tenant right, there being provision for an arbitrator in cases of dispute. The account included the cost of cultivations carried out before leaving the tenancy, standing crops and manurial residues whether of fertilizers applied or purchased feeding stuffs consumed during the latter years of the tenancy; but as farms were vacated at different dates in different parts of the country, though most commonly at Michaelmas or Lady day, custom still played a large part in determining both what things were the subjects of compensation and the basis of assessment.

**Tenancy.**—The British tenancy system possesses many advantages. The handicap that farming is under as compared with other industries lies in the large amount of fixed capital involved in comparison with turnover and in the lag that exists between expenditure and returns. For the farmer who has to own his farm this implies a considerable degree of credit, and in other countries it has generally been found necessary to give some state support to landbanks or other long term credit organizations which will take the burden of the capital outlay on land and buildings. The short term credits required for the conduct of the business proper are supplied by co-operative associations or the banks. Otherwise mortgages rule and mortgages have universally proved destructive to the farmers whenever a run of bad seasons occurs. In Britain the landowner has supplied the cheap capital the industry requires for its permanent equipment, and the banking system so far pervades the community that it can furnish a not unreasonable proportion of the working capital the farmer should have. Even so the farmer would have to work upon a much smaller proportion of borrowed capital than prevails in other business, and in practice in Britain the farmer resorts to a dangerous extent to the tradespeople with whom he deals. The merchants who sell to him his requirements in manures and cakes and buy from him his grain and hay, and the auctioneers through whose hands pass the store cattle he buys and the finished cattle and sheep he has to sell, provide to a very large extent the financial backing of the industry. This custom obviously limits the power of the farmer to buy and sell in the best market, and it was pro-

posed by legalizing the creation of chattel mortgages to enable the banks to accord greater credit facilities. The farmer could then assign his livestock or his standing crops as security for advances.

The tenancy system undoubtedly assisted in the development of British farming in the 19th century, though it produced a certain number of cases of oppression when the power of the landowner to turn out a tenant for causes unconnected with farming remained unrestricted. The condition, however, of success in a tenancy system is the possession by the owner of a real knowledge of, and interest in, the conditions of farming. He (or, in the case of large estates or other interests, his agent) must have considerable technical knowledge, if he is to be a working element of the system, the adviser and leader of his tenants. The declining interest of landowners in agriculture and the inadequate training of so many of the agents employed by them were a main cause of the weakness that the tenancy system displayed and its hampering effect upon enterprise and innovation among the farmers. Many people, therefore, aiming at a return to a system of occupying ownerships pleaded the necessity of freedom for the cultivator and the stimulus of the "magic of property"; though it would be within the experience of those who had occasion to survey the countryside in detail that even if some of the best, so also many of the worst-managed farms are the property of their occupiers. Further in a modern state no ownership system persists; minors, females or men with other interests inherit, and the new owners prefer to let rather than to sell. For these reasons it was argued that the welfare of the industry demanded the state ownership of all agricultural land and a stricter exercise of the continuing owner's interest in good farming.

**Small Holdings.**—Other observers who were impressed by the straits of wage-paying farming, even at the low rates for agricultural labour, sought a solution in a break-up of the larger holdings characteristic of British farming and a return to the peasant system of family farms, still customary in most parts of the world. Even in the depression of the 1920s flourishing colonies of small holders could be found in many parts of the country, and the creation of small holdings was attended by an increase in the production from the soil. For instance in the vale of Evesham grass farms on clay land which were indifferently grazed and yielded but a poor return of milk and store stock, became intensively cultivated for asparagus, plums and other vegetables and fruit; where there had been perhaps one man employed per 100 acres, the small holders would make a thrifty living on 15 acres of the new cultivation Consideration of such cases led to the Small Holdings act of 1908 and to a widespread demand for a general policy of dividing up the land. It was doubtful, however, whether the admitted success of small holdings was a sufficient basis to justify their general application to British conditions. The success of small holdings depends upon two factors. The small holder, being his own master, works harder and more intelligently and for longer hours than the paid labourer; he also throws in the work of his family, often of considerable amount. Large farmers would agree that if they could get from their labourers the quality of work put in by the small holder they could pay wages even higher than the returns obtained by the small holder. Small holders, therefore, are concerned with the production of those things in which manual labour bulks largely, but also they must engage in a branch of the industry that has a rising market, and preferably one that is naturally protected. With their ears to the ground they have been quick to seize upon small things that the large farmer neglects. Milk, potatoes, vegetables, fruit and poultry, and occasionally pigs have been the produce upon which the small holders have depended. They rarely touch the main lines of farming—grain, beef, or sheep and even with milk they often make their profit by combining retailing with production. Thus the opportunities for small holding are limited and the markets they cater for are easily overstocked, although as regards milk and vegetables they had reaped the advantage of a demand that had been steadily rising for years. As a rule small holders require good land and can make little use of the great areas of the chalk and clay soils.

While it is generally agreed that small holdings are unsuited to the production of grain or cattle and sheep breeding, it is argued that even these branches of agriculture could be pursued if they were organized for the co-operative use of machinery, pedigree sires, etc. But this is only equivalent to saying that small holding farming could be successful if imperfectly and by agreement it adopted the methods of large farms. Co-operative farming has not been realized and the mark of the small holder is his independence; as a rule he has only become united with co-operative selling societies when he has been under the necessity of working for an export market. Nor is there necessarily any greater production from land under small holdings; in the instance quoted above the increases are due to a change in system introduced by the small holder. But the large-scale fruit grower or market gardener or milk farmer will produce more per acre and that of better quality than the small holder working single-handed. Organization and the command of capital in the large businesses tell even against the individual attention which is the asset of the small holder; spraying is more suitably undertaken on an extensive scale; clean milk more often comes from the large herds. The greater production per acre of the small holder is often a consequence of the more intensive farming which he is forced to adopt but which would be uneconomic if the labour had to be paid for There are thus two cardinal difficulties attending upon a revival of a peasant system of farming in Britain, one economic, the other social. The economic drawback is the higher capital outlay involved; the creation of a colony of small holdings necessitating expenditure on buildings, roads, fencing, water supply, etc., that is much greater than would be required on a farm of equal area and engaged in the same type of farming. But it is not germane to quote the excessive cost of the small holdings set up after the war, which reached £2,000 and upward per holding, because at that time no farm, large or small, could have been equipped on bare land so as to produce an economic rent. The old peasant holdings inherit in their buildings and equipment, the results of the gradual unpaid labour of many generations and when the holding is sold this accumulated capital is counted cheap, because the price is based upon the farm's earning capacity, not upon what it would cost to reproduce it: hence the prime economic difficulty of building up small holdings *de novo*. The second question is whether small holdings can persist on any large scale under modern conditions. Depending on the basis of the occupier giving his labour cheaply as measured in terms of hours and wage rates, the total cash returns from a small holding are often little or no better than the wages of the agricultural labourer and still less than those of the industrial worker. A certain number of men are always prepared to give this price for their independence and for the chance of getting on, and upon this fact depends the social value, even the necessity, of small holdings. But it cannot be expected that a whole class of the community will permanently consent to lower wages and longer hours. Looking back at the history of British farming the merger of the smaller into the larger farms had always been going on. In other countries peasant farming had persisted longer because of the slower development of the industries, though even in France the peasant was being attracted from the land, and in the U.S. the younger generation looked askance at continuing the family farm. It was in China, Japan and India that the sheer pressure of population maintained the one man farmer at a standard of living barely above the starvation level. Some small holdings are a necessity as a social safety valve; but a general return to small holdings would not solve the problem of increased food production. Farming is an industry like any other and a return to small holdings would be as much a retrograde step as would be a return to hand weaving. Nor is the argument valid that the state would gain by having more men employed upon the land. If extra men are employed on the land because the production has been intensified there is a gain, but if the extra labour has only to make up for an inefficient method there is loss. To prohibit machinery and return to spade labour would ensure the greatest number of men upon the land but the community would lose thereby. That community is the richer which employs the smaller proportion of persons in the production of its necessary food, leaving thereby

a greater number free for the production of clothes, houses, etc., and other elements constituting wealth.

**Industrialized Farming.**—It is obvious that on the large farm very considerable economies of working can be effected, especially from the use of machinery. The cheapening of costs of production depends upon making manual labour more effective. Modern power cultivators are likely to be large in order to secure that speed and depth of working proper to their work; they therefore require large fields to save turning about and only broad acres defray their heavy overhead cost. Farming is no exception to other industries in that large-scale working by its powers of organization and concentration of effort can obtain better work done at a lower cost. The improvement of livestock by breeding and selection is only possible with numbers upon which to work. Buying and selling is better done on a large scale, however much the small holder may be able to obviate his weakness by co-operation. Large-scale enterprise can employ those methods of costing and recording upon which good management is based. In his technical methods the small holder must work by tradition; he cannot afford to experiment and is therefore slower to accept new ideas. Furthermore the land still requires considerable capital expenditure if it is to be put to its best use; and drainage, the straightening of boundaries, and similar wholesale improvements are not practicable except on a large tract of land. It seems inevitable that as intensified production becomes imperative to provide food for a growing population it can only be obtained by large-scale industrialized working. Two conditions, however, must be fulfilled before large-scale farming can be attempted with confidence. First of all a new art of management must be evolved, based upon systematic cost accounting and a critical knowledge of average standard costs. Good farming has hitherto been very much a personal affair depending upon the experience, intuition and determination of the individual. Industrialized farming will always require the qualities of the old farmer—his eye and energy; but it also calls for more calculated management even though farming cannot be standardized like other industries. The other condition of success is the formation of a corps of workers trained for their job and rewarded accordingly. The old type of agricultural labourer was a highly skilled man; much of the work of farming is now being done by men who have been prevented by some defect from entering other walks of life, or by youths who have been left to learn their craft haphazard. Efficiency demands efficient men, for however much machinery may be employed a farm cannot be supervised like a factory. But if the future of agricultural production lies with industrial farming, a bigger unit will be required than the present average British holding. Successful as was the farm of 200–500 ac. as a first step toward intensive production, it has become an uneconomic unit today; it is too small to take full advantage of machinery, is still retail in its buying and selling and demands too large a proportion of its turnover for management. With an average ratio of six labourers to one farmer on English farms, the business is insufficient adequately to pay one man solely engaged in management, and even units of 500 ac. are not large enough. The proper unit is probably something of the order of 5,000 ac., with some hierarchy of managers and under managers into which young men who have been trained for the work could enter in subordinate positions. But it is also one of the handicaps of the present system of British farming that its management is too rarely recruited from school or college as other businesses are. The possession of capital is more often the condition of entry and too often is regarded as dispensing with the need for any technical training; but the industry would be the gainer from a greater leaven of men who began on a more educated plane.

**World Agriculture.**—The depression under which agriculture laboured between World Wars I and II would seem to offer little chance of a reorganization of the industry along industrial lines, there being nothing to tempt the large capitalists to take up food production. This depression was felt in all countries and, as the Economic conference at Geneva in 1927 indicated, it was the outcome of the deficient purchasing power of Europe and of China due to industrial depression. It was perhaps initiated by the deflation policy of the leading states, because it was evident that the low prices were not due to overproduction in the usual sense of the word.

If we exclude from consideration Asia and tropical Africa, as being both self-contained in the matter of food, the population of the rest of the world, constituting roughly the countries inhabited by the white races of mankind, increased between 1913 and 1926 by approximately 50,000,000, or 7½%. The corresponding increase in the area of cultivated land was susceptible of even less accurate estimation, but according to the best figures available was about 36,000,000 hectares. Meantime, however, agriculture was not intensified, rather the reverse, and on the basis of current farming one hectare of land (2¼ ac) was required to produce the food and other agricultural materials consumed by one unit of population. On this showing the increased food production since 1913 had not kept pace with the growth of population. Considering again the countries making returns to the International Institute of Agriculture, the wheat acreage increased in the same period from 109,000,000 to 119,000,000 hectares, the production from 1,029,000,000 to 1,139,000,000 quintals, *i.e.*, nearly 11%. But part of this increase in wheat was purchased at the cost of other crops. In the countries other than Asia and Africa the four chief cereals for human consumption, wheat, rye, barley and maize, taken together, only increased in area by 4% and in production by 5%. Food animals increased, cattle by 12%, sheep by 2%, while pigs declined by 4%, from which an increase of 8% in the meat production may be estimated. These figures lead to the conclusion that latterly the expansion of world food production had not been keeping pace with the growth of world population, even taking account of the relative checks imposed by World Wars I and II and by their consequences The low prices result from the deficient purchasing power of the larger population and from the fact that the greater part of the food production of the world is carried on by peasant farmers. This method of farming can neither alter its production in response to a lower demand nor combine to maintain prices. The men who are engaged in it accept the bad times because in the main no alternative is open to them, and by their capacity to endure hardships and yet persist in production at the low prices prevailing, they ruin the capitalist farmers who have to pay wages. But there are signs that the indifferent returns of peasant farming as compared with wage earning in the industries is beginning to tell in the withdrawal of men from the land. It is clearly happening in the United States and in France, where may be seen in progress the movement that characterized England in the latter part of the 18th century. Peasant farming does not persist when industry and commerce come near and display their openings to the farmer. Moreover the opportunities for creating new peasant communities of farmers have become smaller; great stretches of unoccupied fertile land in temperate climates, such as were settled in the 19th century and provided food for the then unprecedented growth of population, have diminished. The demand for food and other raw materials produced from the land must soon be felt by the still growing population, and any return of industrial prosperity is likely to be followed by a sudden upward rush of prices because there is no margin of overproduction and accumulated stocks behind the present low prices. Production adequate to meet the real needs of the existing population cannot be met by extending the cultivated area but will require an intensification of farming on the land now available. Intensification will only be prompted by better prices and will then best be realized by large-scale farming on industrial lines. (A. D. H.; E. E. Es.)

**World War II.**—The heroic achievements of British agriculture during World War II will long be chronicled. The starting point was a general plan drafted in 1936–37. The basic objective was the production at home of as much as possible of the foods most needed in wartime. The chief means was the plowing of as much grassland as quickly as possible for sowing and planting. An acre of permanent grass feeds only one or two persons, but an acre sown to wheat feeds 20 and an acre planted with potatoes feeds 40. In May 1939 the ministry of agriculture offered farmers a grant of £2 per acre toward the cost of plowing up land that

had been down to grass for seven years or more. Steps were also taken to build a reserve of tractors By the time the war came, 350.000 extra acres had been plowed for planting.

Although the over-all war plan for agriculture was drafted and directed from London, its execution was carefully decentralized On the day preceding the declaration of war, the minister of agriculture appointed county war agricultural executive committees consisting of 8 to 12 local agriculturists for each of the 62 administrative counties of England and Wales The chairmen were carefully selected for their knowledge of local agricultural conditions and practices, their quality of leadership, and the confidence they would receive locally Appointment made the committee personnel responsible to the minister and not dependent on local votes Yet the fact that they were representative of the landowners, farmers and labourers enabled them to work with all the elements of their countrysides in a democratic way Each committee ultimately had a paid executive officer with technical assistants drawn in part from the agricultural education establishments which were closed in 1940. The committees retained the powers delegated to them by the minister but designated subcommittees on cultivation, labour, machinery, land drainage, livestock, horticulture, technical development, feeding stuffs, insects and pests, finance, goods and services, and war damage which supervised the day-to-day work. The county committees also set up 478 district committees. The main reliance was on informal advice and instruction in securing fulfilment of cropping programs, but compulsion after approval by the minister was resorted to in some 3,000 cases where the farmers refused to meet the efficiency standards set by the committees The Agricultural Improvement council, appointed in 1941, was responsible for seeing that the results of research were incorporated in farming practice as quickly as possible.

In 1941 the county committees conducted a national farm survey to ascertain the exact status of British farming and thus provide a factual basis for knowing how far the general standard of farming could be raised. Practically every farm in Great Britain was visited, and the details concerning its condition, management, equipment, capitalization and efficiency were tabulated A census of all farm stock and crops was taken, and a plan of every farm made. The farmers were classified A, B and C—good, second rate and bad, and concerted steps were taken to improve all three categories. This modern Domesday survey not only provided invaluable data for the wartime mobilization of the nation's resources but supplied a blueprint for postwar agricultural planning.

The problem of labour supply was met in a number of ways. The great and necessary increase in arable acreage called for more labour, and yet some 98.000 men left the land to enlist during the war. Provision was made for a Women's land army on June 1, 1939, and some 5,000 volunteers were accepted before the war came. The age limit was set at 17 to 40. The applicants also had to pass a medical examination and give evidence in an interview of their aptitude for farm work. The women were given a month's training at agricultural centres or on approved farms. Their minimum weekly wage was set at 45*s*. Part-time volunteers were also organized; school boys and girls and young students, office and factory workers and retired folk served on this basis Soldiers, including many from overseas, also aided at harvest time. In all possibly 150,000 volunteers helped with the harvest of 1942. In some 50 communities voluntary land clubs consisting of persons who gave their weekends and after hours to farm work were organized. Early in the war the government decided that men must not be allowed to leave the farms for the higher wages of industry, and farm wages were set at a national minimum of 48*s*. and later 60*s*. per week.

Due to war necessity Great Britain became the greatest user of farm machinery of any country in Europe. The number of tractors rose from 52.000 before the war to some 175,000 in 1944. The implement units drawn by tractors increased from 200.000 to 1,175,000. Although combine harvesters had been little used before the war because of the moisture problem, their number rose from 150 in 1939 to 1,500 in 1942. In counties with a scarcity of machinery, implements depots were organized; in others the farmers pooled their machinery in order that their maximum use could be effected The business of firms that contracted to do plowing and similar work expanded greatly. To popularize new machines, demonstrations were held

Many new machines were introduced An Agricultural Machinery Development board was set up to guide this rapid mechanization It consisted of implement manufactures, progressive farmers, representatives of the farm workers and associations for agricultural and industrial research It tested machinery, promoted standardization, provided educational and advisory services encouraged new inventions and ideas, and generally acted as the link between research workers and practical farmers. A national Institute of Engineering functioned under the board. Although large consignments of machinery came from overseas, more than two-thirds of the new units were supplied by home manufacturers.

To meet the food needs much land was reclaimed for agriculture. As the limitations were the scarcity of labour and machinery, it was necessary to take the most promising lands first The ditches on farms were cleaned and many neglected acres reworked. Golf courses, private parks, building sites, bare downs, commons and moors were plowed and planted Bogs and swamps took more expenditure, and it soon became necessary to have the many schemes of reclamation submitted to the government for approval. If approved the government bore half the cost. Inspired by the experimental work of Sir George Stapledon, many pastures of poor quality and rough grazings were reseeded, thus greatly increasing the pasturage for livestock.

As a result of the war effort Great Britain came to produce about two-thirds of the food it consumed whereas before the amount had been barely one-third. It is true that the consumption of some commodities was reduced, but on the other hand the increase was achieved in spite of the loss of more than 7.000,000 tons a year of imported feeding stuffs formerly processed into milk, meat and eggs. This represents an increase of about 70% in the net output of Great Britain's soil. The net arable acreage was increased from 12.000,000 to 19,000,000, the largest total since the early 1870s.

Despite the loss of more than 5 000,000 acres of pasture and most of the feed formerly imported, the dairy farmers broke all previous records and met the demand for fresh milk which came as a result of the National Milk scheme which guaranteed all children under five years, expectant mothers and invalids a pint a day at half price. The flax acreage was increased from 1,600 to 51,000 acres, and in Ulster the acreage was trebled. The production of sugar from sugar beets was sufficient to meet the home ration, though not the manufacturing needs. The wheat and potato acreages were doubled, and the increases in oats and barley were only slightly less. The annual production of vegetables was increased from 2.500,000 to about 400,000.000 tons. The number of sheep declined 20%, pigs more than 50% and poultry about 20%. The number of allotments and gardens in back yards were greatly increased. More than 6,000,000 families raised at least some of their own vegetables and 1,000.000 their own eggs. Although the disastrous weather conditions during the harvest of 1946 and the winter following brought deep gloom to the British countryside, it was hoped that the lessons of its wartime experience and achievement could be salvaged for the future.

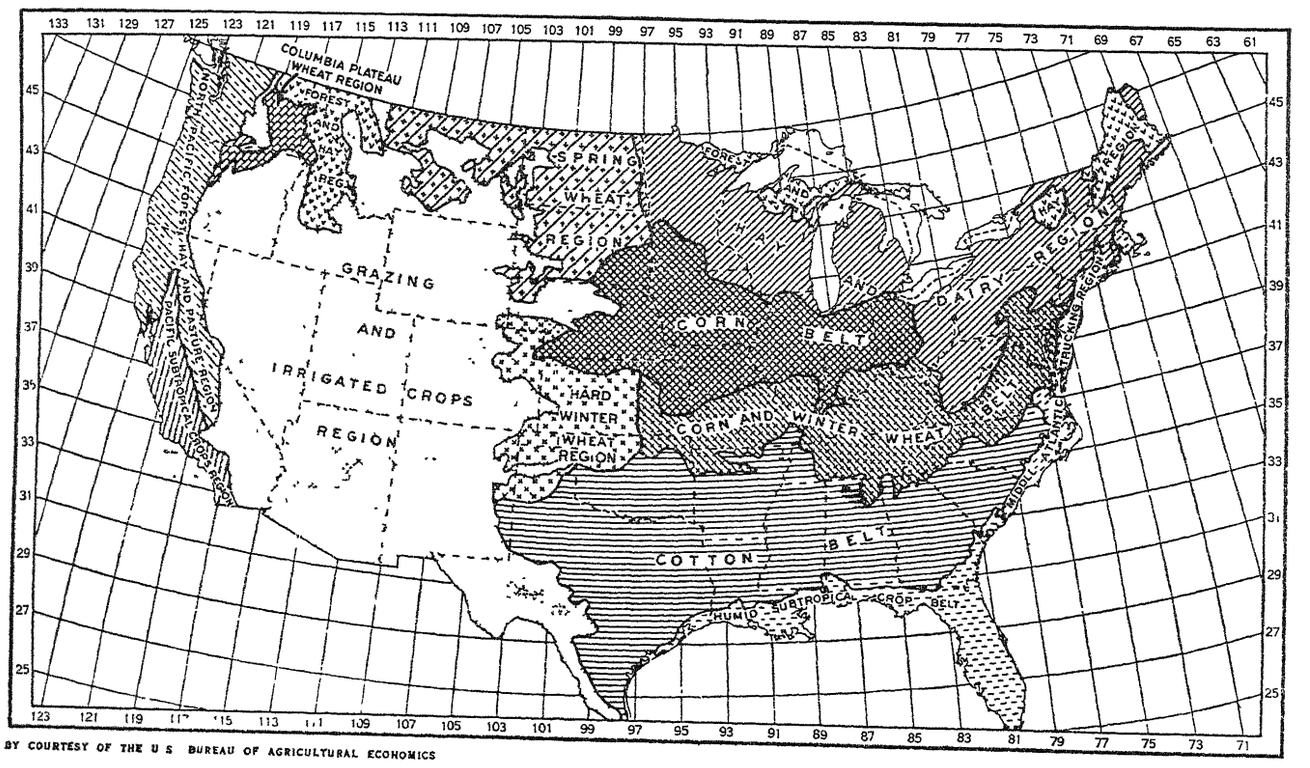
## AGRICULTURE IN THE UNITED STATES

In the Americas the white man's agricultural endeavours extend back only to the middle of the 16th century, but the agricultural achievements of the natives, whom the white man for the most part thrust aside, date back to many centuries earlier. The early Europeans may have willed that the agriculture of the newly discovered continents was to be a projection of that of their homelands, but necessity compelled them to adopt native crops and methods to sustain their colonies It was the union of American Indian and European agriculture that provided the essential basis for the ultimate agricultural development of the new world

Although the pre-Columbian agriculture of the Americas was deficient in certain fundamental respects, it had many contributions to make to the civilization which the Europeans carried around the world. The agriculture of the old world consisted of both cereals and animal husbandry, whereas that of the new world centred about a group of cereals known as maize (corn) and lacked animal husbandry of significance. Neither cattle, horses, sheep nor swine were known in the new world before the coming of the white man. The natives knew that animals could be tamed, but they had failed to propagate them for their flesh or for use as traction power. The new world also lacked the wheel and its common applications in the cart, the pottery wheel and the rotating hand mill. Instead of a plow, the new world used the digging stick and its specialized form, the spade or foot plow. On the other hand, the number of economic plants domesticated by the natives and adopted by the white man for world-wide use is extensive; the more important include maize, tobacco, potatoes, beans, peanuts, squashes, cassava, tomatoes and pineapples—a list that the old world could scarcely rival. The fact that the intruding Europeans found no wild plants of outstanding economic importance not previously utilized by the natives is evidence of their thoroughness in this field of endeavour.



So far as the agriculture of the Thirteen Colonies is concerned, the European background is primarily England of the years 1580–1660. The mother country was then predominantly rural in its way of life. The statement of William Bradford that the Pilgrims were "used to a plaine countrie life and ye inocente trade of husbandrey" serves as a description of the English colonists generally. England of the 17th century was comparatively undeveloped agriculturally. Its great agricultural achievements came long after the founding and acquisition of the Thirteen Colonies.

The earliest efforts of the pioneering colonists to derive a livelihood from the soil can hardly be called agriculture. In general their activities resembled those of primitive tribes in the hunting and collecting stage of development. All of the initial settlements were to a considerable extent dependent on the native plants and wild animals for food until they could ascertain by trial and error what their lands could produce agriculturally.

The natural food resources of the Atlantic coastal plain where the English planted or acquired the Thirteen Colonies varied somewhat according to the latitude, but there was usually an abundance. Berries of various kinds, including blackberries, raspberries, huckleberries, gooseberries, strawberries, cranberries, and fruits such as wild cherries, grapes and crab apples, as well as nuts and certain edible roots were available in season. There was also plenty of fish, oysters and clams, and wild game such as geese, ducks, pigeons, partridges and turkeys, as well as deer. Yet the early colonists were often on the verge of starvation. This suffering amidst what appears to have been abundance has been variously explained, but basically it was because the first settlers found it difficult to revert to a different stage of living; furthermore, it was difficult to transpose and adapt the agriculture of the old world to conditions in the new.

**Colonial Land Policies.**—In 17th century England, landownership was the key to political, economic and social privilege and prestige. It was natural, therefore, that much stress should be placed on landownership in the English colonies. The early explorers had taken possession of practically the entire continent in the name of the king and thus provided him with a vast domain to dispose of as he wished.

Although the ways by which land passed from the king to actual farmers were many and varied, three distinct procedures stand out, namely the manorial system, the New England system and

BY COURTESY OF THE U S BUREAU OF AGRICULTURAL ECONOMICS

FIG. 5.—AGRICULTURAL REGIONS OF THE UNITED STATES

the southern system of headrights.

The attempt to recreate mediaeval manorialism in the new world, although it had long since outlived its usefulness in the old, was suggested by the sheer abundance of land. Although the king made grants of large tracts to friends with a view to their establishing landed estates, their successful development was contingent upon revenue returns from the land. Accordingly the grantees sought to collect quitrents from the actual occupants of the land, but the result was social friction which did not end until the quitrents were swept away during the American Revolution. The land available in other ways far exceeded pressing needs, and those with sufficient initiative to venture to the colonies were loathe to settle voluntarily on manorial holdings, albeit American versions.

Another distinctive procedure of land disposition was the New England system which emphasized group action and theoretically shunned the profit motive. The leading New England colonies were established by trading companies which received extensive grants of land from the crown and which served as, or evolved into, governing bodies. When a relatively old and settled community became crowded, at least according to contemporary standards, a group wishing to move into the wilderness selected representatives to look up a tract, usually contiguous to a settled community, which was deemed suitable for a new settlement. Having found what they needed, they petitioned the colonial government for permission to migrate there. The government, in turn, sent out a committee to examine the tract with reference to its suitability for settlement and to report on the qualifications of the would-be movers and especially of their leaders. If the committee's findings were favourable, the grant was made. It was usually a rectangular area approximating the traditional U.S. township in size.

The group receiving the grant became in essence a quasi corporation and proceeded over a period of years to divide the land in severalty among the settlers. Near the centre of the tract or in some other strategic location a village was laid out, the focal point being a green with the meeting house, the minister's house, a burial ground, a market place and a school. From the green extended the village streets with the house lots, which were plots of sufficient size for a dwelling and outbuildings, a dooryard, a garden and an enclosure for feeding stock. Then a large block of the grant was roughly surveyed and divided into strips which were distributed among the settlers by lot, each family receiving some of the best as well as some of the poorer land. When these "lots" had been developed into tilled fields, a comparable division of another block of the grant was made, and this process of distribution was continued until all of the land received by the original group had been brought under cultivation. The uncultivated land was used as a common pasture by the community, and one or more herdsmen were employed to watch the stock.

This plan of land distribution had important social and political consequences. It developed habits of group action and afforded a compact social life. It facilitated the ideal of a Biblical commonwealth and a Puritan theocracy. The town meeting, at which plans for land distribution were worked out and the officers who cared for the village property were chosen, was a vital factor in the evolution of democracy in America. The system provided an effective and equitable method of distributing large areas of land directly to actual farmers in amounts proportioned to their ability to use the land. It also afforded a security of title that facilitated an orderly settlement of new lands. It provided a sure protection against overlapping surveys and title disputes and made the town or colony responsible for the accuracy of the survey and title. The ease with which new land might be acquired and an independent living assured practically obviated a nonlandholding class and necessitated co-operation among farmers.

The idea of headrights—the granting of 50 acres of unoccupied land to immigrants landing in Virginia—grew out of the view that any person who "adventured" himself to America acquired a share in the Virginia company, but in practice the system changed greatly from the original conception. It was extended to include the members of a settler's family and his household servants, then white indentured servants, and eventually even slaves. Sea captains and merchants who brought in servants or slaves also acquired and sold headrights on their importations Indentured servants received headrights on the expiration of their periods of service Eventually fraud and evasion developed in the administration of the system. Men whose business took them back and forth across the Atlantic customarily received headrights each time they landed in the southern colonies, and the sea captains even claimed rights for their sailors. Ultimately, at least three persons—a captain, a merchant and a planter—might acquire a right on the same individual.

Finally the applicants for headrights resorted to copying names from old record books and tombstones for use on the required forms, and at about the same time the secretary of the colony began to sell headrights for one to five shillings each. The Virginia council, recognizing realities, then authorized the sale of rights to 50-acre tracts for 5 shillings. This substitution, known as a treasury right, was a reversion in legal theory to the right of acquiring land under the Virginia company by the purchase of stock, the commonwealth being regarded as a lineal descendant of the company.

Having secured a headright or a treasury right, the individual located the amount of land to which he was entitled on any part of the unappropriated domain Surveys were supposed to be made by public surveyors, but as most of these officers were inexperienced deputies the possibility of error was always present.

So far as the disposition of land was concerned, the southern system left much to individual initiative. A person could select any desirable tract of unappropriated land and have it marked off by a surveyor under his direction. There was no compulsion to consider the relation of his holding to those of others, and there was ample opportunity to engross the best land, leaving the less fertile soil for the later comers. The system was suited to the needs of a society where large plantations and slave labour, fewer hostile Indians, and a favourable climate permitted the extension and scattering of settlement over the coastal lands In the hinterland the system enabled the pioneers to locate on the good lands adjacent to streams.

**Colonial Farm Equipment.**—The common tools and implements were hoes, spades, scythes, reaping hooks, shovels, carts, harrows and plows, but the supply was probably inadequate in the early settlements.

Although a basic implement, plows were scarce during the first half of the colonial period. The Plymouth colony had none for 12 years and used only hoes and mattocks for breaking the soil The Swedish colony along the Delaware likewise had few tools of any kind until it was taken over by the Dutch in 1655. On the other hand, the farms of Massachusetts Bay had 30 plows by 1636. The early settlers in William Penn's domain around Philadelphia were also relatively well supplied. The possession of a plow made the owner the plowman of his community, and his services were in demand at practically all seasons. Many communities paid bounties to farmers who bought plows and kept them in operation.

The plows of the 18th century were very heavy and awkward contrivances. The mouldboard was not constructed on scientific principles; its iron plating, intended to cut and turn the soil, was rough and uneven, causing excessive friction, and the pull on the drawbar was much greater than on that of a modern plow. It took two men, or a man and a boy, using two or three horses or four to six oxen, an entire day to plow one to two acres. A lighter type of plow was used in cultivating corn. At the close of the 18th century, experiments with improved mouldboards and cast-iron plowshares were being made.

The procedure and the implements used in harvesting, threshing and cleaning grain were comparable with those of ancient Palestine as recorded in the Bible. Wheat and sometimes other small grains were reaped with a sickle. Grass and occasionally grain were cut with a scythe. Grain cradles were introduced in the middle colonies by the middle of the 18th century but were unknown in New England until after 1800. A good reaper usually averaged three-fourths of an acre a day, but if the crop was heavy

he was unable to cut more than half an acre. A cradler could cover 2½ acres In the middle colonies, grain was threshed by treading it out with horses; in New England, the flail was used. After threshing, the grain was winnowed as in Biblical times. A few farmers were experimenting with horsepower threshing machines by 1780.

**Colonial Labour.**—The abundance of free land at the back gate of every community stimulated independence, with the result that there was practically no voluntary hiring out. In the New England and middle colonies, as in nearly all frontier settlements, the problem of a labour supply was met to some extent by community co-operation In the southern colonies, however, where staple crops were raised on large plantations, the need was greater and consequently they resorted more largely to indentured servants and slaves

There were two general forms of indentured servitude, voluntary and involuntary. Voluntary indentured servants were persons who were so anxious to start a new life in America that they were willing to sell themselves for a period of five to seven years to shipmasters or immigration brokers in payment for their passage. German settlers, and occasionally those of other nationalities, sometimes voluntarily indentured themselves in order to obtain funds to make a more advantageous beginning on the frontier when they were able and ready to set up farming for themselves. Most of these "free-willers" came during the latter part of the 17th and early 18th centuries. As a type of immigrant they were practically nonexistent by the time of the American Revolution.

The involuntary indentured-servant group consisted of debtors, criminals deported by order of English courts, and unfortunates who had been kidnapped. The vagrancy laws in England during the 17th century were extremely harsh; the free movement of labour from one parish to another was forbidden; imprisonment was the penalty for debt; and more than 300 crimes were punishable by death Many judges felt that shipping paupers, debtors, vagrants and petty criminals to the colonies was a humanitarian act. Only a few could pay their own passage, and consequently the vast majority were sold, the term of indenture ranging from seven to ten years. Eventually the demand for this type of labour became so great that professional kidnappers seized thousands, particularly in London and other seaport towns, and hurried their victims off to America. During Oliver Cromwell's ascendancy, many political prisoners also were exiled to the new world.

By the terms of their contract, indentured servants were promised food, clothing, shelter, medical aid and the right to own property. For the most part they were well treated, but there were frequent instances of brutality. Masters did not have as strong an economic motive to protect these short-term servants as they did Negro slaves, who were a lifetime investment. At the end of their period of service the redemptioners were to be provided with an outfit as defined in the contract; in the southern colonies they usually had a headright entitling them to 50 acres of free land. The initial transportation cost was fairly heavy, the servants had to be acclimated, and the death rate was high, particularly in the last half of the 17th century. They provided only a temporary and constantly fluctuating labour supply. Of the immigrants who came after the initial settlements were established, probably one-half landed as indentured servants.

Following the example of the French, and more particularly the Spaniards, the English colonies, especially New England, attempted enslavement of the native population, but with little success The first Negro slaves in the English colonies were landed by a Dutch privateer at Jamestown in 1619. From 1635 on, a small number was imported nearly every year, partly from England and New Netherlands, but mostly from the West Indies. Despite the shortage of labour, Negroes were not popular at first, and even in 1690 there were only 5,000 in the tobacco colonies. However, at the end of the 17th century the English government restricted kidnapping and attempted to check the sending of convicts to America. As a result direct slave trade with Guinea developed, and slaveholding began in earnest.

There were about 400,000 slaves in the colonies in 1760, three-fourths of them being in the southern colonies where they constituted about two-fifths of the entire population. They constituted only a small percentage of the inhabitants of North Carolina and Maryland but in South Carolina outnumbered the whites two to one.

In the early days the legal status of the Negroes was vague. The court records of 1661 speak of Negro servants or merely Negroes and never refer to them definitely as slaves. A few were described as servants for a term of years, others were conceded property rights, and some were liberated by the courts as having served their terms. Gradually the Negroes came to be considered servants for life. If well directed, they were capable of tending tobacco, rice, indigo or other staple crops, and with their labour a planter could produce staples at a profit. Yet even at the time of the American Revolution many southerners were urging the abolition of Negro slavery, and had it not been for the rising interest in sea-island cotton and the problem of the disposition of the Negroes in the Charleston district, manumission might have occurred at that time.

Slave labour was poorly adapted to the varied activities of economic life in the northern colonies. Generally speaking, their agriculture could not employ gang labour; nor were there any year-round tasks to occupy the slaves. Slavery did prove profitable, however, to Yankee merchants and shipmasters who shared the monopoly of the slave traffic with the British. New England vessels carried rum and other commodities to the slave coast of Africa and exchanged them for Negroes. This cargo in turn was taken to the plantations of the West Indies or the southern mainland colonies and exchanged for sugar and molasses or tobacco, which was then taken back to the home port. The "middle passage," that is, the trip between Africa and the West Indies, revealed slavery's gloomiest aspect.

The Negroes who had been kidnapped in the interior behind the slave coast were placed in heavy chains and packed in the holds of the ships, where they suffered during the many slow weeks of transit. It was on this sort of trade that many New England fortunes were founded.

**Colonial Crops.**—In growing their first field crops, the early colonists turned to the numerous natural clearings or openings of the Atlantic coastal plain. Many of them were probably old cornfields abandoned by the Indians, while others resulted from the Indian practice of burning underbrush as an aid in hunting. Shortly, however, the colonists had to clear land of vegetation, and this proved a formidable task. It continued to be the first step in making farms until the pioneers of the westward movement reached the prairies of western Indiana and Illinois in the early 19th century. The sunlight had to be admitted to the soil, and the obstructions to tillage, such as stumps, roots and stones had to be removed. Whatever their original conception of the task, the English settlers soon adopted the Indian method of girdling and burning trees in order to prepare land for cultivation.

Maize or Indian corn became the universal crop, owing to its advantages under pioneer conditions of cultivation. Since it was indigenous, there was always reasonable assurance of a successful crop. The manner of cultivating it fitted in with primitive methods of clearing, and therefore it was a labour-saving crop. It also yielded more food per acre than did European grains.

Probably all of the crops familiar to the colonists in their homeland were tried at some time or other. Wheat, rye, barley, oats, buckwheat and peas became important crops, in the order named.

The first attempts to raise wheat were not successful, but by 1640 it became important in New England, judging from the fact that it was then received in payment of taxes. The Connecticut valley with its fertile alluvial soil was the best grain-producing region of New England and may well be designated as the first wheat belt of America. About 1660 the wheatfields of eastern Massachusetts began to be affected by what was called the wheat blast, now recognized as black stem rust. Within a few years it had spread to the Connecticut valley. In spite of the divers explanations given by learned contemporaries, a general relationship between the presence of common barberry and the "blast" was

recognized, and legislation was enacted to encourage the eradication of the bushes Wheat also became important in the middle colonies, to such an extent, in fact, that they came to be referred to as the "bread colonies"

Rye yielded better than wheat on light sandy and gravelly soil and was especially important along the banks of the Delaware, where Swedes and Finns had attempted to found a new Sweden. Just as this particular specialization was due to a racial emphasis, so was the production of oats This grain was produced in abundance as feed for livestock, but only after the Scotch-Irish had come in considerable numbers did the colonists of English descent begin to use oats for human food.

**Colonial Livestock.**—Because the Indians had no animal husbandry, it was necessary for the European colonists to import livestock. Because of distance and the small size of the ships, there was a pitiful scarcity of livestock in some of the settlements during the early years. The losses incident to transit across the ocean were heavy, and it was difficult for the early settlers to provide forage, shelter and protection for the animals. Another factor was the amount of capital behind the particular colonizing enterprises. Plymouth, for example, was without cattle for three years and had no horses or sheep as late as 1627. The Swedish and Finnish communities along the Delaware were also without an adequate number of livestock for many years. The Massachusetts Bay colony, on the other hand, seems to have had a sufficient supply practically from the start.

Eastern North America did not have an abundant supply of indigenous nutritive forage plants, and it was some time before the early settlers realized this fundamental deficiency. Their livestock was dependent for pasturage on the forage in the open places in the woods where fires had destroyed the underbrush or where natural openings occurred. To the early settlers two native grasses, wild rye (*Elymus* sp.) and broom sedge (*Andropogon* sp.), looked promising, but it was soon discovered that although cattle could subsist on these in the summer, the hay made from them had too high a proportion of roughage to be adequate for winter feeding. Eventually the familiar forage plants of Europe and England were introduced, either consciously or accidentally, and once started they spread rapidly. The important hay and pasture plants of today—timothy, bluegrass and red and white clovers—are thus a product of the initial necessity of the livestock industry in the U S.

The need of an adequate supply of hay and pasture continued to be a pressing problem not only throughout the 17th century but during the 18th as well. The cattle were dependent on the annual grasses in the forest openings, and with the increase in numbers of stock the grasses were grazed so short that natural reseeding was prevented. The custom of burning underbrush during the fall months also tended to hold back this process, and droughts further decreased the supply of pasture and hay. As the 18th century progressed, more attention was given to what were called "artificial meadows," that is, uplands seeded with red clover, timothy and other English grasses. This movement was probably inspired by the German-settled communities in the neighbourhood of Philadelphia.

The management of livestock during colonial times, as in most pioneer periods, may be politely described as rudimentary. The problem of confining the animals to definite localities was not easy to solve. Erecting fences required considerable labour and was especially difficult in the middle and southern colonies, where the settlements were largely individual rather than community undertakings. In New England, community settlement made common pasturing possible There the fences were usually around the cultivated fields rather than the pastures and the community hired one or more herders to watch the herds. Hogs, being difficult to confine, proved very troublesome, and in consequence they were probably the subject of more legislation than anything else in agriculture during the colonial period. There was also much legislation concerning brands and earmarks.

Livestock received little shelter in the 17th century and very little more in the 18th. This was largely the current practice in the mother country at that time, and there are indications that the settlers did not immediately realize the effect of the severe American winters on livestock. Besides, the scarcity of labour made it difficult to erect barns or even sheds, and there was also the problem of a feed supply In the course of the 18th century, housing the livestock in winter became a regular practice in New England and New York, but in the colonies to the south, the livestock continued to shift for themselves as best they could There was, however, one striking exception—the thrifty German farmers of Pennsylvania kept fewer animals but stabled them during the winter and fed them well

**Agricultural Policies of the Colonial Period.**—Legislative regulation of American agricultural production began with the earliest settlements. Like the other imperial powers of the 17th and 18th centuries, England expected its colonies to furnish raw materials and serve as a market for the mother country's finished products. Particularly was Britain anxious to stimulate colonial production of commodities for which it was then dependent on other European countries. The measures taken to foster this general policy, commonly known as mercantilism, included tariffs and rebates, subsidies, price regulation, seed distribution and even acreage control. Conforming in large measure with imperial legislation were enactments of the separate colonies seeking to stimulate or discourage the raising of certain crops.

The history of tobacco regulation is probably the most illuminating example of the methods and effects of mercantilism. In 1612 it was found that tobacco could be grown profitably in Virginia, and the colonists, stirred by the high returns, began planting it almost to the exclusion of the essential food crops. In 1616, the governor found it necessary to order each person to plant at least two acres of corn for himself and for each male servant. Tobacco growing continued to increase, however, and the acreage devoted to it was restricted again and again in order to prevent glutting the English market and to ensure an adequate food supply.

Various steps were taken between 1619 and 1652 to give Virginia and Maryland a monopoly of the tobacco market in the mother country. Planting in England was restricted, and Spanish importations were discouraged by discriminatory tariffs. The supply, however, soon exceeded the demand. Prices were depressed, and because tobacco had become the chief exchange medium for Virginia, price fixing seemed particularly desirable. In 1631-32 the Virginia assembly provided that tobacco exchanged for English goods could not be sold for less than 6*d*. per pound, under penalty of imprisonment. By 1639 production had become so excessive that a crop-curtailment and price fixing agreement was made between the colonial authorities and the principal merchants. The crops of 1639, 1640 and 1641 were to be limited to 1,200,000 lb. of good quality, and the merchants agreed to accept 40 lb. for each 100 lb. of indebtedness due them. Viewers were appointed to destroy inferior tobacco, and if necessary to burn excess crops, and in return the tobacco was to be rated at not less than 3*d*. per pound. When it became apparent that monopolization of all the colonial tobacco exports would be ruinous in view of the glutted market, re-exportation to other European countries was permitted. To temper the restriction requiring all shipments to be sent to England and then re-exported, thus subjecting them to English as well as foreign custom and excise levies, an elaborate drawback system by which part of the tariff was remitted on re-exportation was begun in 1631, and after 1723 the entire duty on the re-exported commodity was remitted.

The spread of tobacco growing from Virginia to Maryland and North Carolina aggravated the surplus problem. As a result, various intercolonial pacts were projected with a view to restricting production. More successful were the efforts at standardizing quality by a system of central warehouses and the inspection of export crops by licensed officials. These provisions were enacted in Virginia in 1730 and in Maryland in 1747. Despite all attempts at limitation, the volume of tobacco exports grew from 27,750,000 lb. in 1665 to more than 100,000,000 on the eve of the American Revolution, with a value of £900,000 in 1770. On the whole production was profitable, at least for planters who were able to employ slave labour.

Rice became a money crop before the end of the 17th century and like tobacco was subject to detailed regulation. In 1677 the proprietors of South Carolina stated that they were attempting to secure rice seed for distribution, and an act of the assembly of 1695–96 included rice as one of the commodities that might be tendered in payment of quitrents Considerable experimentation in rice planting took place between 1695 and 1715, and with a surplus available for exporting, the colonists sought the repeal of the English tariffs on rice. Portugal and the West Indies offered profitable markets, but the direct trade that resulted was contrary to the purpose of the navigation acts, and in 1704 rice was added to the list of commodities required to be sent to England and subjected to payment of duty before being re-exported. The Portuguese trade, as a result, was greatly diminished; the colonists memorialized parliament and smuggling increased. Parliament relented in 1730 to the extent of permitting direct trade to any part of Europe south of Cape Finisterre in Spain. This encouraged the rice planters to increase production. Later, however, it became apparent that the northern markets were far more important than the southern; in the decade 1730–39, for example, 74% of the rice exports went to Holland, to Hamburg and Bremen, Germany, and to Sweden and Denmark. Like tobacco, the bulk of the rice crop was then sent to England to be re-exported and through drawback provisions largely escaped British duties. In South Carolina legislative decrees attempted to establish the exchange value of rice, and there were also laws to prevent deceitful packing and to standardize the quality of exports.

To stimulate the production of indigo, instructions to accept it in payment of quitrents were sent to the South Carolina authorities in 1690, and an act passed in 1694 provided special encouragement for growing it. It was not until the 1740s, however, that the indigo industry became important. In 1734 parliament placed indigo on the free list, and a decade later the South Carolina assembly offered a bounty which was in effect for one year. Great Britain, in response to petitions from English clothiers and dyers and colonial planters, granted a premium in 1748 that was continued, although at a modified rate, until 1777. This gave the industry a tremendous impetus, and it is said that the indigo planters were able to double their capital every three or four years. England received the entire indigo crop, which before the Revolution exceeded 1,000,000 lb. a year.

Prior to 1700 Great Britain imported all its hemp and flax from the Baltic countries and Holland. To escape this dependence, a bounty of £6 per ton was placed on colonial-grown hemp, and in 1721 it was exempted from duty, and the bounty was continued for 16 years. These measures had very little effect, but after 1764 there was a revival of interest, and new bounties of £8 per ton of hemp or flax were offered from 1764 to 1771 and of £6 from 1771 to 1778. In addition to these imperial bounties, numerous subsidies were offered by the various colonies. Despite all the legislation these products never became important items of exportation.

Lumbering and the production of naval stores were essentially agricultural pursuits in the colonial period, being carried on mainly by farmers and planters. Despite the abundance of timber these industries did not develop in America until the opening of the 18th century, and then only under the stimulus of the mother country's desire in typical mercantilistic fashion to escape dependence on Baltic imports. A schedule of premiums was drawn up by parliament in 1704–05, and arrangements were made for a surveyor of woods to instruct the colonists in methods of naval stores production. In 1713 parliament further set aside £10,000 to employ skilled people and purchase the necessary tools for fostering the industry.

In all the colonies the production of tar and pitch as well as the lumbering industry were subject to considerable legislative regulation and aid. Qualitative standards were set up with penalties and officials to enforce adherence.

With the Italian Piedmont alone draining more than £200,000 in bullion from England for silk, the efforts to raise this product in the colonies were especially persistent. Numerous mulberry trees were found growing in Virginia, and silkworm eggs were imported by the Virginia company from Italy, France and Spain. The colonial assembly in its first year, 1619, supplemented these efforts by an enactment requiring each man to plant six mulberry trees annually for seven years. In 1654 Armenian silk experts were imported, and in 1656 an allowance of 4,000 lb. of tobacco was voted to one of these experts by the Virginia assembly. Bounties for production were offered in 1658, and in 1662 every landowner was ordered to plant 10 mulberry trees properly fenced and tended for every 100 acres of land he owned. As late as 1730 it was reported that 300 lb. of raw silk had been exported from Virginia. The Huguenot settlers of South Carolina were also interested in the silk industry, and acts of 1736 and 1744 offered sizable rewards for silk growing. Results were meagre, only 651 lb. of raw silk being exported from 1742 to 1755. In Georgia particularly every effort was bent toward stimulating silk production. Foreign experts were sent to the colony; a nursery of mulberry trees was established at Savannah, and four public filatures—establishments for reeling silk—were erected; books and free instruction were provided; and each grantee of a 500-acre tract had to plant at least 2,000 white mulberry trees. In 1740 membership in the newly established assembly was made conditional upon the planting of 100 mulberry trees, and after 1753 no one was to be admitted who did not annually produce 15 lb. of silk and conform to the law requiring a certain number of female slaves to be sent to Savannah for instruction in the silk industry. The high point in Georgian silk exports was reached in 1766–67, when 1,084 lb. were shipped out; by 1772–73 the figure had declined to 485 lb.

Attempts to grow silk were not confined to the southern colonies; similar visionary hopes were entertained in the north. Mulberry trees were common, and many families succeeded in actually producing some silk.

**Colonial Heritages.**—Despite the wide diversity in the geographical settings of the Thirteen Colonies, two generalizations may be made for the colonial period. The social and economic structure of all the colonies was predominantly agricultural, and the small-scale farmer of the period embodied the habits of action and attitudes of mind which were long characteristic of the American people as a national group.

In New England of the 18th century, where commerce and industry were most developed, at least nine-tenths of the population were engaged in farming. In the other colonies the proportion was even larger. The economic life of the southern colonies came to be based on large holdings of land, slave labour and surpluses of exportable staples; the plantation system determined their economies, and the planters dominated their colonial governments. Yet the small farmers with their self-sufficing holdings far outnumbered the dominating group.

It was these small-scale farmers who epitomized American characteristics. They were jacks-of-all-trades; at some time or other and often within a single year, they engaged in hunting, trapping, farming, fishing and even went to sea. They turned to any of the various rudimentary occupations as occasion required. The result was a general facility at tasks rather than the thoroughness of specialization. It was this versatility which served the American people so well as they developed the new horizontal and vertical frontiers that ultimately crossed a vast continent.

These typical colonial farmers, like their descendants, were preoccupied with the practicalities of existence and developed a self-reliance that amounted to intense individualism. The lack of opportunities to travel—either in the physical or intellectual sense—also bred provincialism. The colonial farmers were generally optimistic. With a nondescript past and a humdrum present, they looked to a future that was unhampered by realities. Through the exigencies of their economic existence they came to have a profound faith in work, preferably manual, as the duty of all.

**Agriculture during the Revolutionary Period.**—The small farmers and the frontiersmen were a mountain of strength for the revolutionary cause. They resented the Proclamation of 1763, which they believed would bar further westward expansion; they opposed the prohibition of the issuance of paper money;

they sought more liberal land policies; and they had a sense of local self-sufficiency that was hostile to outside interference. Even more immediate was their resentment of the political and economic domination of the seaboard areas over the colonial governments. The planters indebted to London merchants also adhered to the patriot cause.

On the whole, agricultural life went on much as usual during the Revolution. New England, after the first year of the war, except for the occupation of Newport and a few raids along the coast, was free from invasion New York, New Jersey and Pennsylvania suffered from the depredations of both armies. This was in part compensated for by the liberal prices paid in gold by the French and British for supplies from the farmers, many of whom were only too willing to sell.

American agriculture as a whole was stimulated rather than injured by the war. Blockade runners carried Virginia tobacco to Europe, and the last two decades of the 18th century were comparatively a golden age for that crop. In 1774 production totalled 101,800,000 lb. of leaf tobacco; by 1790 the figure had risen to 130,000,000, with one-half of the southern population engaged in or dependent on tobacco growing. Rice cultivation and export also went on with little interruption. In 1778 the first water mill for cleaning and preparing rice for market was erected on the Santee river. The cessation of imperial bounties cut the ground from under the indigo industry, but cotton came to supplant it. The legislatures of Maryland, Virginia and South Carolina encouraged cotton growing to fill local needs during the war. The same was true of wool production, which was stimulated by interference in trade caused by nonimportation agreements and the outbreak of war.

The exodus of the Tories in the course of the war permitted division of many large estates and the abolition of the last vestiges of the manorial system. As late as 1769, five-sixths of the population of Westchester county, New York, lived on manor lands. In 1777 the continental congress recommended that the colonies confiscate and sell Loyalist property and invest the proceeds in loan certificates. Little external stimulus was needed; New Hampshire appropriated 28 estates; Massachusetts seized the estates of all who sided with England; New York confiscated the 50,000-acre manor of Sir John Johnson, the Philipse manor of 300 square miles, the Morris estate, and other large holdings, which were broken up and sold in 500-acre lots; and Pennsylvania took over the property of the Penn family.

Along with confiscation and land division came the democratization of land tenure. Under the leadership of Thomas Jefferson and his adherents, quitrents were abolished; by 1786 entail, by which land was settled permanently on a person and his heirs, had been made illegal in every state but two; and the other aristocrat-fostering device, primogeniture, the exclusive right of inheritance of the first-born, disappeared by 1791 so that a farmer could hold his land in fee simple and dispose of it as he wished.

Agriculture was affected by the quickening of national consciousness that followed the triumph of the patriot cause. Practical farmers in regions where agriculture was rapidly becoming commercialized began to use gypsum on wheat fields and grasslands. Clover and other cultivated grasses also became fairly common in these regions. Although such changes had no immediate and widespread influence on agricultural production, they indicated the awakening of a new and enthusiastic interest in agricultural improvement. Washington, Jefferson, and many other prominent leaders were familiar, either by correspondence, reading or personal observation, with the revolutionary changes that were taking place in the agriculture of England, and the contrast with the generally haphazard conditions at home was a challenge. To popularize the knowledge of new methods of farming, agricultural societies which became the pioneers in the great task of agricultural education were organized.

**Land Policies to 1862.**—Having won the world-wide conflict which ended in 1763, the British were confronted with the problem of governing and settling the vast empire consisting of what became Canada and the region from the Appalachian mountains westward to the Mississippi river. The halting efforts to solve this problem ended in failure. The treaty of 1783 which recognized American independence gave the United States control of the land south of the Great Lakes and west of the Alleghenies and thus passed the problem on to the new nation. The states with colonial claims to portions of this western land were induced to cede them to the congress of the confederation which enacted the ordinances of 1785 and 1787.

The first of these laid down the basic principles of land disposition to which the United States adhered thereafter, and the second provided the principles of procedure which were generally followed in the government of all territories from the Appalachians to the Pacific ocean.

The federal land policies which developed from the ordinance of 1785 were conditioned by clashes between different schools of political thought, different sections and different economic groups. On one side were those who urged that the government should dispose of its land with prudence; in opposition were those who demanded a generous land policy. The clash of these divergent views constitutes the central theme of the history of U S. land policies during the eight decades preceding the enactment of the Homestead Act of 1862. The conflict tended to concentrate on three specific details: the minimum amount of land to be offered for sale; the price per acre; and the terms of payment.

As early as 1800 the political pressure of the frontier farmers, a group traditionally disposed to demand "liberal" land legislation, had begun to show its influence, and within 20 years their cause had definitely won. Whereas the act of 1796 had specified that the smallest amount purchasable was 640 acres, 80 acres was the minimum unit by 1820, and this in turn was reduced to 40 acres in 1832. The minimum price was reduced from $2 an acre in 1796 to $1.25 in 1820. Furthermore, in practice the minimum price tended to become the maximum price, only a few choice areas being bid for higher amounts at auction time. Thus abundance of land, plus a united public opinion, circumvented the intent of the laws.

Only in one respect was there a nominal reversal of this general trend toward a liberalization of the terms of land acquisition. In 1796 the purchaser was required to pay one-half the price in cash within 30 days and the remainder within 1 year. Four years later the credit terms were considerably liberalized—one-fourth cash, one-fourth within 40 days, one-fourth within 2 years and one-fourth within 4 years. In 1820, owing to the fact that speculators and actual settlers were in arrears amounting to $21,000,000, the credit provisions were repealed and thenceforth immediate cash payment was required.

The history of land legislation during this period also centres about three political and economic issues—graduation, pre-emption and homesteads. The first two were a result of the rapidity with which the public domain had been occupied, and they evolved logically into the third.

The frontier farmers and speculators, having before them what seemed to be an inexhaustible supply of land, selected only the better lands as they pushed westward. Gradually the existence of islands of poorer land which had no buyers became obvious and resulted in a demand to lower its price. Finally in 1854 congress passed a graduation act reducing the minimum price to $1 an acre on land that had been open to sale for 10 years and to 12½ cents on land that had been listed for 30 years.

The pre-emption issue evolved from a correlative if opposite situation. Frontiersmen, becoming impatient of or even being oblivious to the progress of the official land surveys, frequently pushed into the public domain and settled on choice locations without further formality. In doing so they were reverting to the so-called "indiscriminate location" of colonial times With reference to the land laws, these settlers—usually referred to as squatters—were criminals. When the first townships in Ohio were surveyed there were already a considerable number of settlers in the region, and attempts were made to dislodge them with militia. The frontier attitude ultimately prevailed to a large extent. The pioneers banded together into claims associations which maintained a list of each member's holdings; they selected a bidder to

speak for them at the land auctions and attended the sales as a body pledged to ensure the purchase at the minimum price of those lands which were already occupied. Again and again congress passed laws sanctioning the action of particular groups; and ultimately, in 1841, it enacted the pre-emption law by which heads of families, men over 21 and widows were allowed to settle on 160 acres of unsurveyed public land with the right to purchase their holdings at the minimum price when the land was actually placed on sale.

The Pre-emption act of 1841 and the Graduation act of 1854 were, however, merely preludes to the complete triumph of the advocates of a liberal [illegible] in 1862, when the homestead principle was enacted into law.

The general idea of free grants of land to actual settlers went far back into colonial times. The headright system of land disposition as practised in the southern colonies embodied the essential features of the homestead principle. Insofar as the quitrent system was unenforceable, it also resulted in actual settlers acquiring land. There was the further precedent of gifts of land to individuals or groups, sometimes as a reward for services rendered to the national welfare or for services anticipated. In all these three procedures settlers got land without money payments

In spite of these colonial precedents, congress was slow to abandon the conservative and conserving policies adopted during the two decades immediately following the American Revolution. Many regarded public land as a great national resource which should be administered carefully and prudently with a view toward ensuring an income to be used for the well-being of the American people. Many, notably the landowners and manufacturers of the eastern seaboard, opposed liberalization of the land policy. They saw the value of their real estate undermined by the cheaper and newer lands in the west; they also saw western land competing for their labour supply and thus compelling higher wages. The opposition soon rationalized this self-interest and found itself expounding the view that government generosity with land paupe[illegible] and encouraged laziness. Even as late as 1832 the western leader, Henry Clay, opposed any reduction in the price of public land.

In contrast, the self-interest of the pioneer farmers and land speculators in the west generated a notable enthusiasm for cheap and ultimately free land. To secure effective action, they joined forces with city workers who hoped to escape westward and benefit thereby. In the 1840s the National Reform association took the leadership, propounding the doctrine that the public land should be distributed in equal amounts to actual settlers. One of its most effective pamphlets was entitled "Vote Yourself a Farm," and much emphasis was placed on the idea that land ownership was an essential ingredient of the political philosophy to which the United States was dedicated.

At its best the cause of the liberal land policy which came to be epitomized in the idea of free homesteads of actual settlers transcended mere economic self-interest. Many contended that land sold on liberal terms or even given away promoted true democracy. Perhaps the most eloquent spokesman of this view was Senator Thomas Hart Benton of Missouri. It is certain that beneath the passing arguments of the politicians and the pamphleteers lay the conviction that equality of economic power was essential if genuine freedom and democracy were to thrive in the U.S.

The homestead bill introduced by Andrew Johnson passed the house of representatives in 1852, but complete enactment was destined to be held up for a decade because it became a part of the slavery controversy In the first vote a majority of the southern congressmen supported the bill, but as sectional tension intensified they veered away, and final passage awaited the withdrawal of the southern representation from congress after secession.

**Agricultural Settlement, 1776–1850.**—At the beginning of the struggle for independence the colonies had a population of 2,750,000 In 1790, when the first census was taken, there were approximately 4,000,000 people of the United States. Of these, 94% inhabited the Thirteen Original States; only 250,000 had settled in the west of that day—principally in Vermont, Kentucky, Tennessee and Ohio By 1850 the nation consisted of 31 states and a population of more than 23,000,000. The frontier line had leaped the Mississippi river northward into Minnesota and Iowa, and southward into Texas; skipping the Great Plains, it had followed the trail of gold into California. All this had been effected in one lifetime.

The migration, one of the greatest in world history, streamed across the Atlantic and swelled through the settled regions of the east. More than 2,000,000 immigrants swarmed in from 1820 to 1850, and in the next ten years 2,600,000 more arrived. Land was the great magnet. Rich virgin soil, seemingly unlimited in extent and available almost for the asking—such was the common theme repeated by shipping agents and in letters, pamphlets, newspapers and handbills. It was an irresistible temptation to farmers sweating over worn-out lands and to city folk who were restless, adventurous or unsuccessful.

**Agriculture in the Old Northwest.**—Until the prairies of western Indiana and Illinois were reached, the farming in pioneer communities west of the Alleghenies was essentially a repetition of the experience along the Atlantic seaboard during the two centuries of the colonial period. The frontiersman cleared from one to three acres by girdling and grubbing and then planted the field to vegetables and corn. At this stage the family depended on game and other wild products to supplement the food raised Maple sugar was also important, but potash was the only cash product. With more land cleared, additional corn and some wheat were added. Gradually a farm capable of producing surpluses for outside markets was developed.

The responsiveness of wheat to new lands is patent to students of agricultural tendencies, and its development in the region northwest of the Ohio river is an excellent illustration. New York and Pennsylvania were the leading wheat-producing states during the first quarter of the 19th century; but during that time there was a westward shift even within their borders, the Genesee country supplanting the Hudson-Mohawk valley. Ohio became an important producer of wheat during the '30s, but the big shift westward came during the '50s. Whereas Pennsylvania, Ohio and New York—in the order named—had been the top-ranking states in 1849, Illinois, Indiana and Wisconsin took their places within a decade. In that time Wisconsin rose from ninth place to third, and New York and Pennsylvania experienced not only a relative but an absolute decline. By 1860 the five states of the old northwest were supplying about half of the wheat produced in the entire United States. Within the region, the hilly counties of Ohio and the prairies and oak openings of Indiana, Michigan, Illinois and Wisconsin were the areas of concentration.

When the pioneering farmers reached the edge of the prairies in Indiana and Illinois, they hesitated, believing that land which did not support trees was not rich enough to produce farm crops. The lack of a ready supply of wood for buildings, fences and fuel was also a factor. The dependence of these frontiersmen on the rivers as avenues of transport to markets and the scarcity of water and lack of shelter for livestock on the prairies also made them reluctant. The thick and heavily matted prairie sod was a formidable challenge to the customary wooden and cast-iron plows, and from three to seven yoke of oxen were required to break new fields. Even then it was two or three seasons before the grass roots had rotted sufficiently so that the fields could be worked easily. Higher prices for grains after 1845, reflecting conditions in Europe, together with the coming of the railroads, affected the occupation of the prairies. The challenge of the sod led to the development of the steel plow and eventually, after experiments with various fencing materials such as sod walls, smooth wire and Osage hedges, the fence problem was solved by the invention and perfection of barbed wire.

Corn production, like that of wheat, responded, though less quickly, to the pull of the new lands in the old northwest. In general it tended to occupy a belt directly south of the wheat region, but prior to the end of the '60s a corn belt was not clearly delimited except for special areas, such as the rich bottom lands along the Scioto river and the limestone basins of Kentucky and

Tennessee. The census of 1840 revealed Kentucky, Tennessee and Virginia as the leading corn states, but within two decades the centre of concentration had shifted northwestward to Illinois, Ohio, Missouri and Indiana, with Kentucky and Tennessee in fifth and sixth places. By this time Iowa and the eastern parts of Kansas and Nebraska had become important centres. The older states in the east continued to produce corn for their own needs

The corn of this northwestward-moving belt was marketed in the form of whisky and hogs, the first because it was valuable in proportion to bulk and the second because hogs furnished their own motive power. The hogs of the frontier were a special type, essentially a product of the rigours of life in the open and were known aptly as "wind-splitters" or razorbacks. Many pioneers raised several hundred hogs a year. If they were left to feed on the forest mast alone, they put on flesh that was soft and difficult to preserve They also became untractable and lacked the stamina to survive the rigours of severe winters It was therefore essential to supplement the mast with corn, and eventually, as markets developed, corn-feeding and marketing hogs became the basic activities of agriculture in the old northwest.

In the early 19th century the hogs were taken down the rivers on boats to be sold to the plantations in the south or driven overland to eastern markets. At first the farmers drove their own hogs eastward, but gradually a profession of drovers developed and the trade became standardized. Some herds numbered as many as 5,000 and moved eastward at the rate of 8 or 10 miles a day. Although the ultimate destination was usually Philadelphia, Pa., Baltimore, Md., or New York, many herds were taken to the plantations of Tennessee, Virginia and the Carolinas. This method of marketing declined with the development of meat packing along the Ohio, especially centring about Cincinnati, which became known as "Porkopolis." The coming of the railroads was a final factor ending this trade.

The range-cattle industry has always been associated with the frontier, and the region north of the Ohio river was no exception. As early as 1805 George and Felix Renick of Ohio drove a herd of range cattle overland to Baltimore, where they cleared a profit of more than $30 a head. Their success led to other similar drives, and shortly the marketing of range cattle in the east became a well-defined source of cash income for the farmers in the west of that time. The drives were started in the early spring and continued through the summer. Each night the herds were halted at "drove stands," where food and shelter were provided for both the drovers and their charges. Four-year-old steers were driven slowly and sold directly to the abattoirs. Three-year-olds were often sold to the farmers in the hinterland of Philadelphia for feeding. By 1840 the farmers of the Ohio valley had taken over the fattening of their own cattle, and this development became specialized in a zone bounded on the south by the 36° parallel and on the north by the 40° parallel. The bluegrass region of Kentucky and the Scioto valley were the centres for corn feeding, and many of the leaders in this development were former Virginians who had known of similar methods on the banks of the Potomac in the days of Washington.

Eventually these feeders reached out for additional stock from the prairies of Illinois, Iowa and Missouri and from the wheat farmers to the northward. Before large-scale refrigeration, it was difficult to preserve beef in a palatable form, and beef packing did not develop on a scale comparable with that of pork. The eastern cattle drives, therefore, continued long after the hog drives had ceased. The advent of railroads after 1850 brought an end to the drives, and the cattle-feeding industry pushed westward to the corn belt.

**Eastern Agriculture and Western Competition, 1775–1860.**—In the New England and middle Atlantic states the colonial pattern of agriculture continued dominant until the second decade of the 19th century. Cultivation was extensive and exploitive, tools clumsy, systematic crop rotation and fertilizers generally absent, livestock neglected and orchards and woodlands badly managed. Each farm was a self-sufficing unit, growing food for home needs and a scant surplus to be exchanged at the local store for salt and sugar. For the most part tools and clothing were made in the farm home. In New England wheat had been generally abandoned, except in a few favoured regions, and root crops such as potatoes and turnips were noticeably lacking. The prevailing mode of crop rotation was the mediaeval practice of alternating grain, grass and fallow. Implements were few in number, most farmers being able to carry all they possessed on their backs, and the plows were home-made wooden contrivances with a plating of iron strips added by the local blacksmith Oxen were the chief draught animals, and cattle generally were noted more for their hardiness than for beef or dairy production A fundamental cause of this retardation was the [illegible] sets for surplus production.

There were exceptions to the prevailing agricultural backwardness. Between 1801 and 1811 [illegible] were imported from Spain, and the result was a vast improvement in U.S. flocks. Pennsylvania as late as 1840 was the leading wheat-producing state, and considerable grain was also raised in the Hudson-Mohawk valley of New York; the middle states were to a considerable extent the bread states for New England and the south Corn was a leading staple in New England, the output per acre averaging 25 to 30 bushels; in the Connecticut valley, it occasionally averaged as high as 40 or 50 bushels. The Connecticut valley in general was a prosperous farming country still able to raise wheat commercially, and its more progressive farmers used gypsum to restore the soil.

Other outstanding areas were the Narragansett country of Rhode Island, where dairying for exportation was extensive, and the western counties of Massachusetts, which produced grain commercially.

When the rise of manufacturing resulted in the concentration of a large nonagricultural population in towns and cities, a spirit of commercialization became evident in northern agriculture. This change began after 1810; the population of the eastern states increased from 3,487,000 in that year to 6,761,000 in 1840; urban centres of more than 8,000 inhabitants increased from 3 in 1790 to 33 in 1840; while in southern New England all but 50 of the 479 townships had at least one manufacturing village clustering around a textile mill, an iron furnace or some other industry. To meet the demand of this new market the farmer turned to lighter and better-designed agricultural tools; the grain cradle displaced the sickle, the iron and later the steel plow superseded the wooden plow, and the cultivator supplanted the hand hoe. Improved machinery brought increased production and decreased labour time and costs. In Pennsylvania and New York the horse replaced the slow-moving ox as the main draught animal.

Creation of a home market brought a shift from general to specialized farming, and each locality tended to concentrate on the products for which its soil, climate and geographical position were best suited. Market gardening and dairying developed in the immediate vicinity of urban centres, notably around Boston, Mass., New York, N.Y., Philadelphia, Pa., Providence and Newport, R.I. Lands were reclaimed, meadows drained, and dry lands irrigated; the soil was repaired by the planting of clover and the use of gypsum; more labour was hired; and the teachings of the new agricultural societies were heeded. One effect of these changes was a sharp rise in land values; an acre outside of Philadelphia brought $150 in 1837, and near New York land prices in some instances increased fourfold between 1800 and 1840. Tenancy also appeared as immigrants leased truck farms before purchasing their own lands. The production of fluid milk to meet town and city needs became prominent in these decades and continued to expand even after the centre of dairying had moved westward.

Feeding cattle for beef received increased attention in the east, concentrating in the Connecticut valley, which supplied the Brighton market near Boston, and in southeastern Pennsylvania. Specialization in butter and cheese making developed chiefly north of New York city and in central New York after the completion of the Erie canal. Around other cities the sale of fluid milk had largely supplanted cheese and butter production by 1840. Striking improvement was effected in swine husbandry by crossing with improved breeds, but there was no marked geographical con-

centration.

Eastern wool growing enjoyed its greatest prosperity in the decade of the 1830s. The domestic manufacture of woollen goods was firmly established, and, stimulated by protective tariffs, it increased its output and demand for raw materials. In 1837, 28,000,000 of the 38,000,000 lb of wool used in the mills were of local origin. In 1840 the eastern wool growers owned 60% of the country's sheep, but specialization was already well developed. In New England production was limited to Vermont and the hills of western Massachusetts and Connecticut.

Among other changes in northeastern agriculture that came in response to urban needs were the increase in hay production to feed the horses in city and town stables and the growing of potatoes in considerable quantities, particularly in Maine and on Long Island. Farmers also conducted a profitable business in supplying city dwellers with firewood and charcoal and furnishing sand, stone and timber for buildings.

Now that the farmer received a cash income he turned to factories for the clothes, tools and furniture he had formerly made for himself. The decline of household industries had as revolutionary an influence on rural life as the growth of industrialization had on the formation of a wage-earning class. As self-sufficient farming waned, long-established habits and traditions in thinking and living were uprooted. The family as an economic unit became less important, with all that implied for rural mores; farmers' sons and daughters began migrating to mill towns to take up a new way of life. Those who remained behind developed a taste for urban standards of living. Others were stirred to action and turned westward.

These changes did not appear overnight, and they did not affect all farmers uniformly. Ingrained habits tended to keep many farmers in the old ways of producing what they needed for their own uses, buying and selling little. Lack of working capital was another serious hindrance; the farmer marketed his produce once a year and had to maintain his family on the returns until the next year. The country store was the chief source of short-time credit, and interest rates were high because losses were frequent. Where the farmer realized a surplus, he preferred to invest in lands, in larger homes, or in outside enterprises, rather than in labour-saving machinery. Mortgages increased noticeably in number after 1830, but the money was used for paying bills or in outside speculation instead of for financing farm improvements. The imperfect organization of markets was another obstacle; the country merchant, the chief middleman for farm produce, performed his function badly and at a high cost.

While the eastern farmer was still adjusting himself to commercialized agriculture he was faced with a second transforming influence, namely, western competition. The Erie canal was opened in 1825 and brought steadily increasing quantities of foodstuffs to the eastern markets, but the pressure greatly increased after the railroads reached beyond the Alleghenies. By 1850 there were 7,000 miles of railroad in the country, largely concentrated in the northeast and northwest; and ten years later Minnesota, Iowa, Nebraska and Kansas were already pouring surpluses eastward. From the west came wool, wheat and pork in such quantities and at such low prices as to discourage local production. Sheep raising in southern New England declined nearly 50% between 1840 and 1850, with a further drop of 35% in the next decade. The products of the eastern wheat growers, suffering from soil deterioration and crop blights, could hardly compete with the products of fertile lands newly opened in the west; and by 1840 flour from western wheat was used generally in New England, not only by city folk but by farmers as well.

Before the advent of refrigerator cars the effect of competition in beef and pork production was somewhat tempered, although by 1859 half the beef supply of Massachusetts came from outside New England, and Philadelphia received 32 552 tons of livestock from Pittsburgh over the Pennsylvania railroad. Between 1840 and 1860 the number of swine in Massachusetts, Rhode Island and Connecticut fell from 306,000 to 167,000.

Serious as these inroads were, they by no means crowded out eastern production entirely. If local farmers almost completely lost the markets for wheat and wool and to a lesser extent for live cattle and hogs, the advantage of their proximity to industrial centres could not be overcome altogether. More attention was given to growing vegetables and supplying fluid milk. Cheese and buttermaking increased, and by 1860 New England and the middle Atlantic states accounted for 70% of the country's cheese and close to 50% of its butter. In New York, the nation's leading dairy state, production was centred in the Mohawk and Hudson valleys, with some expansion into the central counties; Vermont led in New England, although Litchfield county in western Connecticut was famous for the fine quality of its cheese; while southeastern Pennsylvania supplied butter and milk for the Philadelphia, Wilmington and Baltimore markets.

The New England and middle Atlantic states grew more hay and forage in 1860 than in 1850, although their share of the country's total dropped 15%. Corn production increased in New England between 1840 and 1850 but then declined; on the other hand, the crop of potatoes in Maine in 1860 was almost twice as large as that of 1850. A final example of adaptation to city needs was the increased planting of orchards. Horticultural societies were formed, improved varieties of apples planted, and old native fruit trees grafted. By 1847 Oneida county in the Mohawk valley shipped nearly 18,000 barrels of apples.

Eastern agriculture thus underwent two major changes by 1860. In response to the growth of a home market, farmers gradually shifted from self-sufficing to commercialized agriculture between 1810 and 1840. While this change was still taking place, the farmers on rich virgin soil to the westward began to ship their produce by canal and railroad to eastern markets. As a consequence, local farmers were forced to specialize in articles such as milk, butter, cheese, vegetables, fruit and hay, which, by reason of their perishability or bulk, escaped western competition and enjoyed a ready market in the expanding urban centres close by.

**Southern Agriculture to 1860.**—Despite an ever-growing rivalry with the northwest, the south continued as the principal centre of commercial agriculture from the Revolution to the American Civil War. Its pre-eminence, however, was due chiefly to the rise of cotton production and its expansion into the old southwest. Tobacco fell off greatly in relative importance. Indigo cultivation waned, having suffered a death-blow by the removal of the British bounty. Rice farming underwent a transition incident to the adoption of the tide-flow system. Hemp and flax later became crops of some importance in Kentucky and Missouri, and sugar growing achieved considerable success in Louisiana. It was cotton, though, and particularly cotton on western land, that predominated.

Cotton had been grown in the southern colonies but only for domestic use. Yet the revolution in textile manufacture in England that made possible mass production of cotton textiles for a world market created a comparable demand for the growth of cotton fibre. Soil and climate favoured the green-seed short-staple variety, but separation of the seed from the lint was difficult, slow, and expensive because the fibre had to be cut or torn away. Sea-island cotton, a longer-fibred variety, was introduced in 1786. Its seeds were easily removed by running the fibre between rollers that revolved in opposite directions. Although sea-island cotton brought high prices and was raised, often on a large scale, until the American Civil War, the acreage devoted to it was limited, as it could be successfully grown only on the lowlands along the southeastern coast.

The cotton gin invented by Eli Whitney in 1793 solved the crucial problem incident to large-scale production of the green-seed short-staple cotton, and its invention marked a turning point not only in southern agriculture but in U.S. history. Upland or short-staple cotton became the largest commercial crop in the south and the basis of its economy. Each decade cotton production approximately doubled. In 1800, 73,222 bales of cotton were produced; in 1840, 1,347,640; and in 1860, 3,841,416. It overflowed the domestic market and became the largest single export of the United States. In 1810 cotton represented 23% of the value of total exports, or a little more than $66,000,000; by July 1, 1860, it had increased to 61%, or more than $333,000,000.

As the south concentrated more and more on cotton growing, it also offered a larger market for northwestern grain and livestock products.

Cotton expansion revived the moribund institution of slavery, as the growing of cotton was very well adapted to unskilled supervised gang labour. In the five years before the federal prohibition of the slave trade became effective in 1808, South Carolina alone imported 39,000 slaves, and by 1860 its slave population increased to 57.2% of the total population. Another institution, the plantation, similarly became prominent, and the three together—cotton, slavery and the plantation—acquired a dominating influence over the political and social as well as the economic structure of the south.

Cotton growing centred first in the tidewater region of South Carolina and Georgia Many planters shifted to it from indigo and rice cultivation. The methods of cultivation were crude and wasteful, not because of slave labour but because land was abundant and cheap. Squandering natural resources was as characteristic of the southern planter as of the western pioneer Cotton growers reached out to the Piedmont of North Carolina and Virginia and then turned southwestward. The War of 1812, the acquisition of east and west Florida, and the removal of Indians to reservations beyond the Mississippi were, in part at least, due to cotton. The belt of heavy black and brown loam soils in Alabama and Mississippi were found to be unsurpassed for cotton, and this region long remained the foremost cotton district in the world. Nevertheless the migration of cotton planters continued westward into the second area of great cotton production along the lower Mississippi. Even these conquests were not enough, and the land-hungry and restless pushed on to the prairie region of Texas.

Until 1821, more than one-half of the cotton had been grown in Georgia and South Carolina. By 1850 Alabama ranked first, Georgia second, Mississippi third and South Carolina fourth. In 1860 Mississippi, Alabama and Louisiana produced more than one-half of the total cotton crop in the United States, while Texas grew more than South Carolina. In the north, when the Atlantic seaboard states could not meet the challenge of western agriculture, industrialization was intensified; in the older south no such compensating factor was present, and economically it fell steadily behind the southwest. Land values declined, and Savannah, Ga., and Charleston, S.C., were supplanted by New Orleans, La., and Mobile, Ala., as trade centres. Even by 1820 the areas first devoted to cotton presented a sorry picture of eroded lands, bare of vegetation except for scrubby growths.

The southeast blamed its decline on the tariff, the federal banking policy, the lack of credit facilities and heavy taxation. All these factors were present, but the problem was primarily accentuated by the rapid westward expansion. Despite many pamphlets, resolutions and conventions, a movement for industrial diversification did not progress far because the capital available was too closely tied up with landed investments, while the labour supply, whether slave or "poor white," needed wholesale readaptation. As an alternative, the southeast sought to establish itself as the trade centre for both the southwest and the northwest, but the former developed its own ports, and the latter became tied to the northeast by railroads.

Attempts were made to adjust and reform the agriculture of the southeast to the changed conditions. John Taylor "of Caroline", sought to halt the retardation of Virginia agriculture by improved methods of farming, and Edmund Ruffin sounded an even more clarion call to check soil depletion. When the older region first felt western competition, it found itself with too much slave labour. Transfer of that surplus westward only strengthened the competition. Finally, in the '40s and '50s, when labour was needed for agricultural diversification, slaves were scarce. The old south could not afford to pay $1,000 to $1,400 for prime hands and was outbid by the southwest, where fertile lands yielded a much greater output per unit of labour. In desperation the southeast sought a reopening of the slave trade; though the attempt failed, slave smuggling probably was increased. More important for later development was the fostering of progressive methods such as deeper plowing, the introduction of new crops, the increased use of labour-saving devices, and the importation of improved breeds of livestock Agriculture' journals and societies were begun and fairs and exhibits held. General farming became a prominent feature of the agriculture of the border states, and just prior to the outbreak of the American Civil War Virginia achieved a moderate prosperity as a result.

Tobacco, the south's chief colonial staple, reached its height in the 1790s, when more than half the population of Virginia, Maryland and North Carolina were engaged in or dependent upon its cultivation In 1790 it ranked first on the list of U.S. exports, with a value of more than $4,000,000. After 1800, however, it declined rapidly in relative importance, and production remained stable until 1850. The disturbed trade conditions resulting from the Napoleonic Wars, the post-1815 attempt of England to stimulate domestic tobacco production or West Indian importation, the high duties imposed by countries of continental Europe anxious for revenue, and the competition of Cuba, Sumatra and Colombia all helped to undermine the position of United States tobacco in the world market

At home, meanwhile, cotton was outbidding tobacco for the available land and labour. By 1850, tobacco production had passed its lowest point and had begun to revive. Flue curing supplanted the old-fashioned, charcoal-fire, open-air methods, while a new yellow-leaf variety, lighter than the old varieties, won popular favour. Between 1850 and 1860 production doubled, North Carolina and Virginia being affected most.

Tobacco, like cotton, expanded to new fields in the west in the years before 1860. Extractive pioneer cultivation laid waste the older lands, while low prices on the world market called for decreased production costs. It was cheaper to move to fresh soil than to struggle with worn-out fields. Virginia maintained its lead till 1860, but Kentucky was close behind, and Ohio, Tennessee and Missouri had made a considerable advance. Two important trade and manufacturing centres for tobacco, Louisville, Ky., and St. Louis, Mo., developed in the west.

Sugar production, like that of cotton, grew from insignificant proportions to outstrip tobacco in importance. The cane was introduced into Louisiana by Jesuits from Santo Domingo in 1751, but it was not until the last decade of the same century that the crop was grown on a commercially significant scale. The sugar district centred along the rivers and bayous of southeastern Louisiana, where the soil was rich and the growing season was sufficiently long for the plant to mature. Despite fluctuations caused by floods and occasional early frosts, production increased from approximately 20,000 short tons in 1823 to 270,000 in 1861. Unlike most other southern staples, sugar enjoyed the protection of a high tariff, and the industry was highly mechanized; sugar production expanded slowly, either to the west or to the east. It did extend over to the Brazos river area of Texas and to a lesser degree into Florida and Georgia, but in these states it was relatively insignificant. Though the industry was limited in the main to Louisiana, it affected the southeast. Many South Carolinians, for example, migrated to Louisiana, taking their labourers with them. By 1860 the sugar plantations were using a total of 180,000 slaves; this involved a considerable drain of labour from the Atlantic seaboard and sent slave prices upward.

Rice continued to be a leading agricultural crop along the coast of South Carolina and Georgia until the American Civil War. Production increased threefold from 1820 to 1850 but suffered a distinct decline in the next decade. In the banner year of 1850 South Carolina and Georgia together accounted for almost all the rice grown in the United States. There was some development of the industry in Louisiana, Mississippi and Alabama, but it was of little consequence. Rice planters felt western competition most when they had to bid for labour on a market dominated by the cotton growers of the southwest.

Almost from the first settlement of Kentucky, hemp raising was found well suited to the rich limestone areas. Unusually favourable prices from 1826 to 1828 stimulated production, and hemp growing expanded into middle Tennessee and, during the '30s into the rich valleys of Missouri. The cotton industry had a

considerable interest in hemp, since it was manufactured locally into baling cloth, rope and clothing for Negroes. In 1859 Kentucky and Missouri together produced more than three-fourths of the 57,000 tons of hemp raised in the United States. Soil deterioration, scarcity of labour and Russian competition, however, had already influenced Kentucky to turn more toward wheat growing and cattle raising

While the south raised all of the cotton, rice and sugar grown in the United States and more than 80% of the tobacco, its other crops also ranked high. It produced more than 50% of the country's corn, more than 70% of the peas and beans, 94% of the sweet potatoes, and a little less than 30% of the wheat. In producing each of the principal classes of livestock the south ranked higher per capita than the United States as a whole. Kentucky was famous for its race horses, horned cattle and Hampshire hogs, while Virginia was a leader in sheep raising. Eighty-six per cent of the south's general farming was located in the border states in 1859

In the south the landowning class was divided into gradations of small, intermediate and large farmers, and small, intermediate and large planters. In 1850 only 18% of the south's 569,000 farms and plantations were actually plantations, and this estimate includes as "plantations" many thousands of small cotton and tobacco holdings with but one or two working hands. Even in the black belt of Alabama almost 80% of the nonslaveholding landowners, who in 1850 constituted 44% of the region's agricultural population, owned farms ranging up to 200 acres. Of the slaveholding landowners, more than 50% owned 10 or fewer slaves and 500 acres of land or less, which classed them as farmers. Together the small planters and the slaveholding and nonslaveholding farmers owned approximately 75% of the landed wealth in the black belt—the so-called stronghold of the plantation system. As late as 1860 only 348,000 families out of a total of 793,493 white and free Negro families owned slaves in the south.

While the yeoman farmer was more truly characteristic of the landholding class, even in the ante-bellum south, it was the 2% holding plantations with more than 50 slaves that dominated economically, politically and socially. Not until the American Civil War overthrew this planter aristocracy did the yeoman or dirt farmer begin to come into his own.

**Agricultural Revolution.**—The transformation of U S. agriculture from a simple, pioneer, and largely self-sufficing occupation into a modern business organized on a scientific, capitalistic and commercial basis is frequently referred to as the agricultural revolution. Simultaneously industry shifted from hand labour in homes to machine production in factories, and local markets were transformed into a world market.

Like all striking changes this vast reorientation of the country's economic life did not begin suddenly or in all regions simultaneously. Even in the colonial period many American communities concentrated on the production of surplus crops for distribution in markets beyond their confines. During the latter half of the 18th century the agriculture of England underwent a similar change, and the accompanying desire to utilize improved methods in order to make farming profitable was not without influence in the United States in the years following the American Revolution. While the forces of the so-called agricultural revolution had long been at work in the United States, it was not until the last half of the 19th century that they began to manifest a fruition which captured general recognition. Careful study of the agricultural history of the United States reveals that its agricultural regions and perhaps also the country as a whole experienced a number of quickenings of agricultural progress and that it would be more accurate to speak of a congeries of agricultural revolutions rather than merely one Perhaps, indeed, the over-all agricultural revolution is the adjustment and response of agriculture generally to world opportunities and conditions that followed the so-called Europeanization of the world, a process which included the merging of the old and new world agricultures

The forces underlying the so-called agricultural revolution in the United States may be summarized as follows: The passing of the public domain into private ownership by means of liberal land policies; the completion of the westward movement of settlement; the invention and popularization of improved farm implements and machinery; the extension and development of transportation facilities; the expansion of domestic and foreign markets, the migration of industries from the farm to the factory; the resort to conscious and concerted political organization and action by farmers in an effort to retain an equitable place for agriculture in the economic structure of the nation; and the establishment of agencies for the promotion of scientific knowledge relating to agriculture—agricultural societies, agricultural fairs, periodicals for farmers, the federal department of agriculture and agricultural colleges and experiment stations. These forces, it should be emphasized, did not reach their maximum impact simultaneously, and some of them were still operating with increasing potency after World War II.

**Passing of the Public Domain.**—Under the Homestead Act of 1862, the head of a family or a person over 21 who was a United States citizen or had filed intention of becoming one received title to 160 acres of the public domain after proving five years residence, by evidencing good faith by cultivation and paying a nominal registration fee. After 6 months (raised to 14 months in 1891) the entry might be commuted by the payment of the prevailing minimum price, usually $1.25 per acre. Later amendments permitted veterans of the Union army and of succeeding wars to count the time of their military service against the five-year residence.

The homestead policy was not well adapted to much of the public domain to which it applied. By this time agricultural settlement had reached the eastern edge of the Great Plains. To the west the average rainfall ranges from 10 to 18 inches and falls much lower during seasonal and cyclical dry spells. The farming techniques developed for the humid soils to the east were unsuitable for these new conditions. Effective land utilization required dry farming, grazing or intensive cultivation with irrigation, but 160 acres was too much land for irrigated farming and too little for grazing or dry farming.

Moreover, the homestead method of distribution was merely an addition to others already authorized by previous statutes, and the result was an incongruous land system. The cash sale of land was continued to 1891, and more land was bought than homesteaded. Between 1862 and 1871, the railroads received about 125,000,000 acres as subsidies, and homesteading was not permitted except 20 to 40 miles back from the projected routes. By the Dawes Act of 1887, modified by the Burke Act of 1906 and later measures, about 100,000,000 acres of Indian lands were opened for sale. More than 7,000,000 acres were given to the states in accordance with the Land Grant College Act of 1862.

With such a vast empire of land purchasable, speculation and land monopolization became rife. Syndicates purchased land in large blocks and generally secured the most desirable lands. Actual settlers might get free lands that were less fertile or less advantageously located or buy at prices set by the speculators, the railroads or the states.

The administration of the land laws was even less satisfactory. Fraud became rampant, and the general land office which supervised disposal of the public domain did not have the organization, the personnel, or the public and official backing to ensure careful and honest administration.

Efforts were made to adapt the homestead principle to special situations. Measures were passed from time to time to aid homesteaders affected by droughts. In 1873 the Timber Culture act promised 160 acres to any homesteader who kept trees growing not more than 12 ft. apart on 40 acres, and 5 years later this minimum was lowered to 10 acres. In 1909, the size of homesteads was increased to 320 acres in portions of eight western states. A quarter of the tract was to be cultivated, and no commutation was allowed. In 1916 the maximum was increased to 640 acres for farmers who wished to raise stock.

By the Desert Land Act of 1877, 640 acres of arid land could be purchased at $1.25 per acre provided the buyer irrigated and cultivated at least one-eighth of the tract. In 1890 the amount

that could be secured in this way was decreased to 320 acres. In 1878 the Timber Cutting act and the Timber and Stone act authorized for the first time the legal cutting and purchase of timber from the public domain.

As the 19th century neared its close, the rapid passing of the best farming lands into private hands, the rise of tenancy, and the emergence of land monopolies gave strength to the principle, long dominant and submerged, that the nation's natural resources should be conserved. In 1891 the Pre-emption and Timber Culture acts were repealed, the amount obtainable under the Desert Land act was reduced to 320 acres, the period that must lapse before homesteads could be commuted was extended to 14 months, and the president was authorized to reserve timber areas. In 1894 the Carey act granted 1,000,000 acres to certain states provided they were settled and irrigated. In 1902, under the Reclamation act, the federal government began to initiate irrigation projects on the public domain. Following the publicizing stimulus of President Theodore Roosevelt, there was steady progress in the reclamation, conservation and scientific use of land after the beginning of the 20th century. In the 1930s the National Resources Planning board studied the classification of all land in terms of inherent characteristics, current use, capacities, recommended use and program effectuation.

The Taylor Grazing Act of 1934 authorized the withdrawal from private entry of about 80,000,000 acres not suitable for crop farming and their use as grazing districts. The next year all the remaining unreserved public domain of any value was withdrawn from private entry. In 1936 the Soil Conservation and Domestic Allotment act authorized farmers to preserve and maintain soil fertility.

**Completion of Agricultural Settlement.**—By 1850 the westward-moving frontier of settlement had halted at the edge of the Great Plains, because of the Indian policy inaugurated a generation before and because the unoccupied region presented a challenge to the accepted methods of agricultural conquest. There were already isolated islands of settlement in California, the Willamette valley of Oregon, and Utah. Within 40 years the entire territory of the trans-Missouri west was occupied and began to add to the surpluses of agricultural products and to serve as a growing market for manufactured goods.

The population of continental United States numbered 23,191,876 in 1850 and 62,947,714 in 1890. By 1920 it totalled 105,710,620. That is to say, the population increased by two and one-half times in 40 years and by four and one-half times in 70 years. Immigration supplied 31,406,943 from 1850 to 1920. Reduced to simple terms, this increase in population meant more farm surpluses; but it also created a greatly expanded home market for agricultural products.

The population of the United States continued to be predominantly rural after World War I, but the rapid increase and ultimate triumph of urbanization predestined the future of the United States to a quite different social and economic configuration. The census of 1880 showed that the rural population, including towns and villages with fewer than 2,500 inhabitants, numbered 35,797,616, or 71.4% of the total population. This was more than the population of the entire country in 1860. By 1910 the rural population numbered 49,806,146, which was 54.2% of the total. By 1920, however, the census showed that the majority of the U.S. people lived in towns and cities—48.6% being classified as rural and 51.4% as urban.

**Mechanization.**—The process of agricultural mechanization began in the 18th century and is still going on. The implements used in the colonial period were largely operated by hand, supplemented to a slight extent by animal power. The first half of the 19th century brought initial inventions and improvements in machines operated by animal power for use in planting, cultivating, harvesting and threshing. The reaper was especially important because it was used at the crucial period in the production of grain crops when delay often spelled disaster. The general displacement of men by horses developed most rapidly between 1860 and 1910. The substitution, however, had hardly begun before manufacturers of farm machinery began to experiment with the use of mechanical power in place of animals. Considerable use of steam tractors in preparing and planting land was made on the prairies of the middle west. By 1905 the practicability of using the gasoline engine for power had been demonstrated. Its use on tractors was quickened by World War I, but the adaptation and perfection took place in the '20s and '30s. Almost as revolutionary in their effects were the use of automobiles and trucks; they put rural communities in closer touch with urban life and facilitated marketing. Beginning in the '30s the government program of extending electrification to farms brought illumination and power for indoor machines that did much to decrease household and farm drudgery.

Mechanization of farming brought many changes. The productivity of farm labour was increased (one estimate says 400%), and manpower was released for other activities. The farmer who could buy expensive machinery had an advantage over those who could not, and it became increasingly difficult for the man without capital to farm. The production of agricultural products and the output per capita was greatly increased. The result was the accentuation of the problem of overproduction. Mechanization prolonged extensive as opposed to intensive cultivation and gave large-scale operations an advantage. An increasing number of acres once devoted to the raising of feed for animal power could be used for the production of human food. The isolation and much of the drudgery of farm life disappeared. (*See* AGRICULTURAL POWER AND MACHINERY.)

**Improved Transportation and New Markets.**—As a generalization it may be said that the roadbuilding era of the early 19th century was superseded by a canal building and river transportation era. This, in turn, was displaced in importance by the building of a national network of railroads which provided rapid means for marketing the surpluses of the farms and ranches. In the 20th century attention was given to surfaced roads that would facilitate the farmers' access to primary markets. The increased speed of trains, specialized livestock and refrigerator cars, and systems of through transportation widened the area of competition for many commodities and hastened regional specialization. This development of a national transportation system was accompanied by comparable modernization of the marketing organization.

The transportation and trading agencies enabled an enormous volume of farm commodities to pass from the farms to the urban consumers, both in the United States and in other countries. By 1900 agricultural production was also providing more than four-fifths of the raw materials manufactured. The repercussions of U.S. agricultural exports on European economic life were far-reaching. The labouring classes were provided with cheap and abundant food, but unless protected by tariff walls the European farmer was unable to compete. The results of this situation were mirrored partly in the tremendous migrations from Europe to the United States during the 1870s and 1880s, partly by the flocking of farmers to cities, and partly by agrarian movements that clamoured for governmental relief in various forms. After the '80s, new agricultural regions were opened in Russia, Argentina, Australia and Canada, and their produce began to compete with U.S. foodstuffs in the European markets. As an exporter of foodstuffs the United States began to decline in importance after 1900. The domestic market continued to expand, but relative overproduction and maldistribution continued to plague the U.S. farmer.

**Migration of "Industries" from the Farms.**—Until well into the 19th century a distinctive feature of the U.S. farm was economic self-sufficiency. The average farm produced and processed practically everything that it needed—food, clothing, furniture, soap, candles and the many other articles essential to the farm family. The transfer of their manufacture from the farms to factories is a significant aspect of the transition from self-sufficient to commercial agriculture. It was, furthermore, the central fact of both the agricultural and industrial revolutions. This cityward migration of industries resulted in vast changes in the technical processes of manufacturing. The growth of urban communities centring about factories greatly enlarged the markets

for agricultural commodities. Specialization in agriculture was also intensified.

The industries transferred from the farms to factories may be grouped as follows. The processing of foods; the making of textiles and clothing, including boots and shoes; and the preparation of tobacco and other products for use. The first group includes slaughtering and meat packing, flour milling, the manufacture of butter, cheese and other dairy products, and the canning of fruits and vegetables. Many new industries were developed, notably the processing of beet sugar, the baking of bread and pastries and the making of confections. In 1860 flour and grist mill products ranked first among the food-manufacturing industries. By 1919 the slaughtering and meat-packing industry had taken first place. In that year the products of all food industries constituted 20% of the total value of all U S manufactures.

**Political Organization and Action.**—The great increase in agricultural trade did not bring prosperity to the farmers. Instead the three decades following the end of the American Civil War brought acute distress to many. The census of 1880 showed that the proportional share of agriculture in the nation's income was decreasing steadily. In addition to the problem of relative overproduction, the appreciated gold standard resulted in a general fall in the price level from 1875 to 1897. The farmer, by the nature of his industry, was unable to adjust his production to depressing conditions as quickly as other businesses could.

As the farmers expanded commercial agriculture, physical limitations bore down on them. Those who extended cultivation into the semiarid Great Plains were confronted with seasonal failures. Deforestation, improper drainage and faulty tillage resulted in destructive floods and unscientific cropping practices exhausted the soils in the humid regions.

All agricultural regions had particular difficulties. Eastern farmers had to compete with the cheap production of the west or turn to specialties. Western farmers were burdened with mortgages held by eastern investors. The price of land increased disproportionately to the returns that could be expected.

Living conditions on farms came to reflect the relatively small returns upon the farmer's investment and the meagre awards for his labour. The educational and recreational opportunities fell behind those of the cities. It was also apparent that the farmer was less influential in state and national politics and that policies were being shaped more and more in the interests of the rising industrialism.

The situation called for concerted organization if the farmer was to have a relatively favourable position in the national economy, but this was not forthcoming. Traditionally the farmer held back from common action. The dispersal of the farming population, the number of farmers involved, their varied and competing commodity interests, and the lack of leaders tended to thwart organization. (*See* FARMERS' ORGANIZATIONS.)

In spite of these difficulties, the distress became so real and pressing that a number of class-conscious farmers' movements were generated. Together they came to be known as the agrarian crusade. Each movement reflected the particular need and the special centre of distress of its time.

The first in order of time was the Granger movement (*see* GRANGE, THE) of the '70s in the upper Mississippi valley where the farmers had special grievances. With no regulation of their capital structure, methods and rates, the railroads and the marketing agencies that they dominated practised discriminations which so inflamed the farmers that they organized independent and antimonopoly parties between 1873 and 1876 and thus gained control of state legislations which enacted laws to fix and regulate the rates charged by railroad and elevator companies. Although lack of precedents and adequate information thwarted these attempts at regulation, the contention that such corporations were public in nature and therefore subject to governmental regulation was upheld by the supreme court of the United States. In 1887 the responsibility for railroad regulation was assumed by the federal government The grangers sought to assuage their grievances against wholesalers, distribution and credit agencies, and merchants by organizing co-operative buying and selling agencies of their own. Co-operative credit and insurance companies were also developed on a modest scale. A co-operative industrial program which called for the manufacture of a full line of farm machinery and household implements fell far short of expectations.

The Greenback movement from the late '60s onward sought to check deflation by stopping the contraction of the amount of greenback money in circulation and by having the war bonds redeemed in legal tender This type of inflation interested eastern labour and the debtor farmers of the middle west but failed to win support from the agricultural interests generally. A temporary price rise in the early '80s ended the movement, but the basic problems of currency, credit and marketing remained unsolved.

In the 1880s a variety of local organizations that developed spontaneously among the small farmers and tenants of the southwest and the wheat farmers of the northwest became the basis of the Farmers' Alliance movement, whose general program emphasized co-operative activities. In addition, the southern group proposed a federal system of warehouses and elevators where crops might be deposited in return for negotiable certificates and loans in legal tender up to 80% of the local price of the product The northwestern group urged a federal land-loan agency that would make loans upon farm land up to half of the appraised value at 2% per year. In spite of leader emphasis the members of the alliances turned to politics and eventually became part of the Populist movement.

The extremely depressed economic conditions of the early 1890s bore particularly hard on farmers and led to the formation of the People's or Populist party. Its three main objectives were reform and regulation of the disposal of the public domain in the interest of actual settlers, strict regulation of corporations and public ownership and operation of transportation and communication facilities, and raising the price level by federal note issues and the restoration of the free coinage of silver at the old ratio of 16 to 1. In the campaign of 1896 the Populists joined with the Democratic party under William Jennings Bryan and lost.

**Science Applied to Agriculture.**—In the colonial period there were individuals who applied their powers of observation to farm problems and even conducted experiments to ascertain the ways of nature and to develop better methods. In the latter half of the 18th century, leaders who sought to spread information concerning the findings of improvers and innovators began to form agricultural societies to function as educational media. In the first third of the 19th century agricultural fairs and farm periodicals were developed as additional instrumentalities in the movement. (*See* AGRICULTURAL SOCIETIES AND SHOWS.)

Public aid for agricultural improvement came slowly because the seemingly inexhaustible abundance of natural resources appeared to negate the necessity. Before 1860 state aid was limited mainly to small grants to agricultural societies to assist them with their fairs. By the '50s a few states had boards that collected information deemed pertinent to farmers. The cumulated necessity of regulating the food-processing industries and of combating animal and plant diseases and pests systematically led to the creation of state departments of agriculture in the '70s.

In the national realm, President George Washington had urged the creation of a U.S. counterpart of the board of agriculture then functioning in England, but it was not until 1839 that a unit of the patent office received appropriations with which to collect and distribute seeds and to assemble and publish information. This work was continued by the separate department of agriculture created in 1862. In addition experienced staff members conducted scientific research. The department's regulatory powers became important in 1884 when a bureau of animal industry was created to administer meat inspection and check livestock diseases. In 1889, because of increased functions and the potentialities of the agrarian unrest, the department was given full executive status and a secretary who served in the president's cabinet. The rapid and profound changes in agriculture necessitated the expansion of research, regulatory and educational functions in the department. (*See* AGRICULTURAL RESEARCH.)

There were a fair number of undertakings which offered formal instruction in agriculture during the first half of the 19th century, but it remained for the Morrill Act of 1862, which granted land endowments to state colleges offering courses in agriculture and mechanic arts, to provide the basis for the extensive system of agricultural education and research that was peculiarly American The institutions receiving the benefits of this act were slow in finding their particular place and function. In the end it was the experimental work that won recognition for the agricultural colleges from scientists and eventually dirt farmers as well. (*See* AGRICULTURAL EDUCATION )

**The Main Agricultural Regions.**—During the last half of the 19th century, the various systems of agricultural production were adapted to geographical conditions, and in consequence relatively stable agricultural regions evolved. Each region became dominated by one commodity, grown in conjunction with subordinate products and with specialties having preference in limited areas. Market opportunities, mechanization and scientific methods accelerated this regionalization.

The humid subtropical crops belt consists of comparatively undeveloped low coastal plain bordering the Gulf of Mexico and extending from Matagorda bay, Texas, to Charleston, S C. The soils have been very influential in determining which of the subtropical crops are grown in the different parts of the region and together with local differences in temperature cause the region to be divided into subregions.

The rice subregion centres in the heavy clay coastal prairie of southeastern Texas and southwestern Louisiana. In the 1880s settlers from the grain-growing middle west migrated there and began to grow rice. Irrigation was provided by artesian wells and pumping stations. About 1900, the federal department of agriculture introduced Japanese varieties that flourished. The use of machinery in the cultivation and the harvesting of the crop made the cost of production so low that the area could compete in practically any market. In 1902 mechanized rice growing was also undertaken on the grand prairie of Arkansas and in 1908 in the Sacramento valley of California.

Sugar-cane production was centred on the rich alluvial soils of the Mississippi delta after its successful introduction there near the end of the 18th century. Even after the abolition of slavery, it continued to be a large-scale capitalistic enterprise. In view of the high production costs, the industry was especially dependent upon tariff protection. The U.S. acquisition of competing areas, namely Puerto Rico and the Philippines, and a reciprocal treaty with Cuba brought new difficulties. The disastrous floods in 1874, 1882 and 1884 necessitated large-scale levee construction. After 1900 special attention had to be given to the checking of diseases and the development of new varieties. The muck soils around Lake Okeechobee in Florida also proved well adapted to the production of sugar cane.

Favoured districts of the remainder of the humid subtropical crops belt gradually developed importance as producers of subtropical fruits and trucking crops. Winter vegetables and citrus fruits flourished in Florida, and the problems were those of adaptation to local conditions and specialized marketing.

The boundaries of the cotton belt are determined largely by climate, but the density of cotton production is largely dependent on the soils. The northern boundary follows the line of 200-day average frost-free season and of 77° F. average summer temperature. The southern boundary is the line of 10-in. autumn rainfall. In the decade following the American Civil War, the attempt to continue the plantation organization with hired labour of freedmen failed, and cotton growing was shifted to small units of land operated under a share-cropping system. The crop lien given in return for the advance of supplies chained the cropper to the landlord or local merchant, but they in turn were dependent on the bankers and commission men. As cotton was a standardized marketable commodity, diversification for the market and even for subsistence was discouraged. Production was inefficient, and the costs remained relatively high. Falling prices hit the cotton south as hard as the wheat area of the west in the '80s and '90s.

The demand for cheap fibre and the utilization of cottonseed in the manufacture of feed, oil and fertilizer led to the expansion of cotton growing westward to the subhumid line in Texas and northward to the frost line in Oklahoma, Arkansas and Tennessee. Simultaneously the use of commercial fertilizers revived the industry in Georgia and the Carolinas. By 1880 cotton manufacturing began to be established in the southern Piedmont, and eventually these mills fabricated more than half the cotton crop.

Cotton growing was imperilled by the ravages of a devouring beetle known as the boll weevil which crossed the Mexican border into Texas in the 1890s and progressed eastward across the cotton belt. To offset the losses, cotton farmers turned to other crops to some extent, but the main relief came from the introduction of improved methods of cultivation and hardier varieties of cotton. This campaign for improvement directed by Seaman A. Knapp provided the basis for the extension service of the federal department of agriculture.

Tobacco growing is widely distributed in the United States, but the cultivation of the main types has centred in the borderland between the south and the north which is sometimes known as the corn and winter wheat belt. The bright-leaf flue-cured tobacco, used in cigarettes, became the major crop in northern and eastern North Carolina, and Durham and Winston-Salem became great centres of tobacco manufacture. The heavy dark burley tobacco needed for foreign markets centred in western Kentucky.

The middle Atlantic trucking region extends along the Atlantic coast from Charleston, S.C., to Portland, Me. It developed mainly because of three conditions: the large markets for fresh vegetables and fruits provided by the large cities within or near the area; its sandy soils that respond to cultivation and fertilization; and its mild climate with a long frost-free season.

The hay and dairying belt includes the portions of the cool humid northeastern United States and adjacent Canada in which agriculture generally is more important than the forest industries and dairying is the dominant interest. The southern boundary is approximately the line of 69° mean summer temperature in the west and 70° to the eastward. With the growth of industrial centres the eastern portion of the region gave increasing attention to the production of fluid milk. Wisconsin became the leading cheese-producing state, and Minnesota and Iowa specialized in buttermaking.

Between 1880 and 1914, dairying made notable progress in production, processing and marketing. Better dairy cattle were introduced and developed. The silo was adopted as a method of preserving corn and its green fodder for feed, and increased attention was given to forage crops. The cream separator simplified a hitherto time-consuming process, and the butterfat tester provided an accurate and quick method of measuring butter content. The condensing process was perfected. Milking machines were invented. Dairymen pioneered successfully in the co-operative processing and marketing of their products. Between World Wars I and II the dietary habits of the U.S. people gave greater emphasis to the value of dairy products.

The wheat regions developed in accordance with the conditions necessary to wheat growing. Wheat was the characteristic crop on each frontier across the northern and western United States. The prairies of Illinois were the main centre from 1860 to 1880. Minnesota ranked first during the next two decades and then gave place to North Dakota. During World War I Kansas became the leading centre. Winter wheat was continued as part of the general farming of the borderland corn and winter wheat belt. In contrast, hard spring wheat continued northwestward in a region having the bare requisite humidity and also to the Pacific northwest. This movement was made possible by the development of new varieties of wheat, resistant to drought and rust, and to innovations in methods of cultivation, especially power mechanization.

Corn continued to hold the basic place in crop systems and stock raising that it had early assumed in the colonial period and was, therefore, grown in all cultivable belts. Like wheat, its main centre of production moved westward but, unlike the other cereal, it halted when it reached the prairies of the middle west which

were predestined by the unique combination of soils and summer temperature and humidity to become the corn belt. The large-scale preparation of hogs and cattle for market followed corn into the region

Because of the importance of corn and hogs to the region, special attention has long been given to the improvement of both In the 1890s corn breeders followed the mirage of uniformity and symmetry, and it was not until after World War I that the importance of hybridization came to be recognized. In response to consumer demand, the old heavy lard hog was evolved into a younger light bacon type. The value of hogs made the checking of virulent diseases imperative, but it was not until 1913 that a preventive serum was developed for hog cholera.

The valleys of central and southern California and the coast south of Santa Cruz have been designated the Pacific subtropical crops region. The Spaniards utilized three institutions—the presidio or military establishment, the pueblo or colonial settlement, and the mission—to occupy the region. Of these the last was by far the most significant as missions became centres of agricultural development. Although the friars introduced the fruits of their Mediterranean homeland to the mission gardens, cattle raising was the dominant occupation during the Spanish-Mexican period, 1769–1848, and continued to be until [illegible] ended it as a distinctive industry. Sheep raising recovered from the droughts, reached its peak in 1874, and then began to decline. In the years 1870–90 wheat farming reached bonanza proportions in the San Joaquin valley. Although the gold rush following 1849 stimulated attention to fruit raising, the experimentation and development necessary to capture a national market took place only after 1869, when the first transcontinental railroad was completed. By 1890 the people of the region knew what crops to emphasize and where to raise them, and the solutions of the problems of water supply for irrigation and of marketing were generally evident.

The humid portion of the Pacific northwest and also its irrigable valleys, like semiarid California, became a region of special crops. The Hudson's Bay company had farms to supply its helpers with food. The pioneers who migrated over the Oregon trail and settled in the Willamette valley in the 1840s also carried on general farming. Once the prairies were occupied, the high cost of clearing land in the region became and remained a big factor. It was necessary, therefore, for each valley and locality to specialize on crops which, by virtue of quality, could hold their places in the national markets.

The grazing and irrigated crops region was initially merely a strenuous barrier to those of the east who wished to reach the gold of California and the fertile lands of Oregon. As the gold production of California declined, the miners turned to the unoccupied valleys and mountain ranges to the eastward. Their rush into what is now Colorado laid the basis for permanent settlement there. The miners' occupation of Nevada, Arizona, New Mexico, western Montana, Idaho and eastern Washington took place during the American Civil War. The need of food supplies for the mining camps prompted the beginning of agriculture in the valleys. The completion of the Union Pacific railroad in 1869 brought a flood of hunters who exterminated the buffalo and thus left the Great Plains for occupation by the range-cattle industry. The success of the Union Pacific led to the building of four other transcontinental lines. Thus, the region, in contrast with the east, had facilities for rapid transportation prior to, rather than after, intensive settlement and exploitation. For two decades after the American Civil War, a vast cattle industry thrived on the open range. Then the railroads brought homesteaders and other land seekers who disrupted the range and forced the cattlemen to shift to a ranch basis. The invention of barbed wire for fencing in 1874 facilitated this step.

The fact that much of the land received less than 20 inches of rainfall annually foredoomed the transplanting of eastern ways of agriculture and necessitated the development of new methods and crops. Irrigation and dry farming became important in the United States for the first time.

**World War I.**—In terms of agricultural production and marketing, the war period extended from the fall of 1914 to the spring of 1921. During the first two years production was not markedly stimulated, and the trade in certain commodities, notably cotton, was depressed. With the entrance of the United States into the conflict in 1917, an unprecedented program of agricultural production, especially of cereals and meat, was undertaken. To this end the new extension service created by the Smith-Lever Act of 1914 and the county-agent system acting with farmers' organizations were utilized.

Wheat was the cultivated crop most needed. The price was fixed by the federal government to encourage its production The acreage increased more than 50% and its production 38%. More than one-quarter of the expansion was in the corn belt at the expense of other small grains, corn and grassland; most of the remainder was in the Great Plains. The demand for fats greatly stimulated hog production; more than 1,000,000,000 lb. of pork were exported in 1918 as compared with a prewar 5-year average of 450,000,000 lb. The dairy industry also expanded notably to supply the export demand for concentrated milk and the larger domestic demand which resulted from increased purchasing power.

The war years accentuated a complicated economic situation for the farmers. Their returns varied greatly according to commodities; the prices of wheat, hogs and tobacco were relatively high, whereas those for horses, cattle, butter and eggs were relatively low. Inflated values largely accounted for the general high level of prices, and this influence increased markedly the farmers' living and production costs. Land values rose as much as 70%.

**Postwar Depression.**—The price decline that began in 1920 affected agricultural products first and hardest. Following the withdrawal of credits, the foreign markets disappeared, and yet the farmers' fixed costs continued. Instead of curtailing output, the agricultural industry sought to meet the situation by increasing production even though it had to sell at low prices. The industrial and financial boom of the middle '20s brought only a limited improvement to agriculture. At the boom peak in 1929 the index of [illegible] prices was only 91% of the prewar level, and it had fallen to 50% by Feb 1933. Gross farm income, which had risen from $7,000,000,000 in 1914 to $17,000,000,000 in 1919, fell to a little more than $5,000,000,000 in 1932.

This agricultural distress of the 1920s affected the various regions at different times and with varying degrees of intensity. During 1920–22 the spring-wheat region was the centre of distress and protest. In 1923 the decline in the hog market resulted in farm foreclosures and bank failures in the corn belt. Although the south early sought relief for specific products, it was not ready to demand a general program of relief until 1926.

Beginning in 1921 an agricultural bloc of western and southern congressmen sponsored emergency and long-time measures of relief and stabilization for agriculture. In 1923 intermediate credit banks were authorized to make short-term loans on livestock and farm commodities. The McNary-Haugen plan proposed to dispose of the farm surpluses abroad and to finance this procedure by an equalization fee assessed on the producers, but bills embodying the plan were twice vetoed by President Calvin Coolidge. In spite of the fact that the nation had shifted from a debtor to creditor status, the successive administrations from 1921 to 1933 placed much emphasis on protective tariffs to establish and maintain cost-of-production prices for the leading farm products in the home market.

Although the administrations were against large-scale government action, continued distress led to the creation of the Federal Farm board in 1929 to support and promote co-operative marketing associations as a means of controlling output and thus ensuring profitable returns.

**New Deal Measures.**—The agricultural policies of the Franklin D. Roosevelt administration from 1933 to the outbreak of World War II passed through several stages. To meet the emergency of price collapse, the Agricultural Adjustment Act of 1933 authorized extreme measures for the reduction of production and compensation payments from a tax on processors. The success attending the program for cotton, wheat, corn, hogs and tobacco in 1933 led to its expansion in 1934 to include beef and dairy

cattle, peanuts, rye, barley, flax, grain sorghums, sugar beets and sugar cane. At the same time submarginal farmers were encouraged to withdraw from commercial production, and the administration initiated a policy of reciprocal tariff agreements with other countries to encourage the export trade in agricultural products. Despite the widespread criticism of crop reduction by the consumers who were saddled with its cost and despite the disadvantages attending it, the economic conditions of the farmers rapidly improved. Supplementary legislation expanded the credit facilities for farmers and attacked the problem of tenancy. In Jan. 1936, the supreme court held the act of 1933 unconstitutional, and the administration had to turn to other media of action.

The danger of shortages and the tragic results of soil destruction were emphasized by the droughts that culminated in the dust storms of 1935 and 1936. The soil conservation service was created in 1935 to conduct soil erosion surveys and carry out preventive measures. The Soil Conservation and Domestic Allotment Act of 1936 provided $500,000,000 for the preservation and improvement of soil fertility, the promotion of the economic use of land, and the protection of rivers and harbours from soil erosion. For two years co-operating farmers received direct aid, after which responsibility for the program was shifted to the states that enacted suitable legislation and provided a conservation plan acceptable to the federal department of agriculture.

A comprehensive and long-time program was provided by the Agricultural Adjustment Act of 1938, which emphasized and provided for an "ever-normal granary." As in earlier acts, the initial aim was the establishment of prices for wheat, cotton, corn, tobacco and rice at a level in relation to the cost of commodities bought by farmers in 1909–14 (for tobacco the parity base was 1919–29). The act provided machinery for soil conservation and balanced output, loans, marketing quotas, marketing aid and promotion and parity payments. A new feature was crop insurance for wheat.

During the years 1933–38 economic planning was carried further with respect to agriculture than for any other economic interest. The federal government assumed responsibility for determining both production and prices as well as maintaining soil resources and providing most of the farmers' credit needs. Before the full program as outlined in 1938 could be tested, agriculture as part of the national economy became involved in a global war.

**World War II.**—The production record of U.S. agriculture during World War II was phenomenal. The increase in total production from 1939 to 1944 was twice as large as during the preceding 20 years. The gross farm production in 1944 and again in 1945 averaged 124% of the prewar years 1935–39. The wartime achievement was accomplished without significant expansion in the crop acreage and in spite of shortages of labour, machinery and other supplies. Even though one-fourth of the food output went to military and other emergency uses, there was food enough in 1944 and 1945 to provide the civilians with a per capita food consumption about [illegible] than before the war. Although extremely favourable weather was a factor, it accounted for only about one-fourth of the total increase. The main motivation for increased production was the doubling of the prices received by farmers for their products which resulted from the wartime needs, but the large-scale increase was made possible by a number of factors that had been building up potential production capacity during the 1930s.

Mechanization was the most important factor. The number of tractors on farms increased from less than 250,000 in 1920 to more than 2,000,000 in 1945. The shift to mechanical power during these years released for the production of commodities for human use about 55,000,000 crop acres, or about 15% of the available cropland, once used to grow feed for draught animals.

Another important factor was the increased use of lime and fertilizer. In terms of plant nutrients the total consumption of commercial fertilizer in 1944 was 85% above the quantity used in the years 1935–39, and the use of lime was nearly three times as large. Official estimates placed the increased production resulting from the additional use of lime and fertilizer in 1944 at about 15% of the total increase in output after 1935–39.

The adoption of improved crop varieties was another important source of increased production. The use of hybrid seed corn added 400,000,000 bushels to the 1944 crop. New varieties of oats were introduced in the corn belt, the Great Lakes states, and the southern states. The war years also accelerated the adoption of more productive and more nutritious legume hays.

The production of crops especially needed during the war was greatly expanded. The harvested acreage of hemp for hard fibre was increased from 1,246 acres in 1935–39 to 146,200 acres in 1943. The acreage of soybeans harvested for seed and for crushing in 1944 was 241% of that acreage in 1939. The acreage of flaxseed for oil in 1943 was more than three times the average of 1935–39. The production of peanuts, beans and peas for human food was greatly increased. In addition to these crops which affected large areas, there were others whose production was concentrated in small areas, notably vegetable [illegible] castor beans and some pharmaceutical plants grown to alleviate war shortages.

A number of forces accounted for the increased marketings of livestock and livestock products. The current feed production permitted an increase in livestock. In addition, the shift to mechanical power released additional feed for animals that are grown for human use. The supply of feed was also more balanced with respect to protein and other nutritive elements. Livestock production also increased in output per unit of feed.

The wartime production record was achieved despite a decreasing labour supply. The total farm population dropped from 30,000,000 in 1940 to 25,000,000 in 1945, and the number of farm workers was 8% less in 1944 than in 1935–39. Nevertheless, by utilizing all the mechanical power available and working longer hours, the farmers and their families were able to develop the potential agricultural production capacity of the nation and make it the great food arsenal of the United Nations.

**Agricultural Chemistry.**—Agricultural chemical investigations in the United States are conducted in all the bureaus of the federal department of agriculture except those concerned exclusively with economic research and action and regulatory programs, in the agricultural experiment stations of the states and territories, in the universities and research institutions, and in the laboratories of the food-processing plants and industries which utilize agricultural products.

At first the agricultural chemists were almost exclusively concerned with the chemical control of commercial fertilizers and the study of fertilizer action upon the growth of plants. The study of cattle feeds for regulatory and research purposes was next taken up, and finally, with the passage of state and federal pure-food laws, the diet of man began to be investigated—first for the prevention of adulteration and then for the improvement of human nutrition. The sequence of plants, animals and man, although seemingly illogical as regards importance, was the natural order of research development. The passages of state and federal laws governing the purity of insecticides increased further the regulatory work of agricultural chemists, and most of the experiment stations shortly found control work so disrupting to research that the former was separated from the latter and transferred to state chemists.

The policy of separation was also adopted by the federal department of agriculture in 1927 when the inspection control of food and drugs, insecticides, tea and naval stores was transferred from the bureau of chemistry to a purely regulatory Office of Food, Drug and Insecticide Administration. By this time agricultural chemistry had become so vast a field of research that scientists spoke and worked in terms of its subsidiary sciences rather than the subject as a whole.

The lines of chemical research emphasized in the various experiment stations depended naturally upon the predominant agricultural needs of their states. Chemical investigations relating to dairy products were stressed in New York, Wisconsin, Minnesota and other leading dairy states; those concerned with flour in the wheat-growing states; those upon sugar production in the cane-growing states of the south and the beet-producing states of the west; and those upon corn in Iowa and the other large corn-grow-

ing states.

Examples of pioneer specialization with more than regional applicability were the lysimeter studies upon percolation in soils in Tennessee, the research on alkaline soils in California, and the studies of vegetable proteins in Connecticut and of animal calorimetry in Pennsylvania.

Among the more important chemical projects of the federal bureaus were investigations upon soils, fertilizers and nitrogen fixation; foods and food technology; human and animal nutrition; plant constituents; insecticides and fungicides; chemistry and technology of tanning materials, leather, paper, fabrics, sugar, starch, oils and fats; meat, dairy and forestry products; storage of cereals, vegetables and fruits; deterioration of agricultural products; spontaneous combustion; dust explosions; and methods of agricultural chemical analysis. In the 1930s greatly increased attention was given to studies of the industrial uses of agricultural products, by-products and wastes. Simultaneously the research work was largely transferred from Washington to the Agricultural Research centre at Beltsville, Md., and to four regional laboratories at Wyndmoor, Pa., Peoria, Ill., New Orleans, La., and Albany, Calif.

During World War II agricultural chemistry research made many notable contributions to the war effort, including the development of penicillin, synthetic rubber and plastics, the dehydration and compression of vegetables and eggs, and the stabilization of nitrated cotton for explosives; many of these and similar projects will be redirected to peacetime needs. (For the early history, *see* Charles A. Browne, *A Source Book of Agricultural Chemistry* [1944]; for the United States, *see* Charles A. Browne in the American Chemical Society's *Journal,* v. 48, no. 8a, pp. 177–201 [1926].)

**Experiment Stations.**—In the United States agricultural experiments were early conducted by the agricultural colleges, but not until 1875 was the first experiment station with state support established. It was located at Middletown, Conn., under Wilbur O. Atwater and later was moved to New Haven with S. W. Johnson as director. The University of California next provided for a station at Berkeley, under the leadership of E. W. Hilgard. Other states followed, and by 1887 there were 18 stations.

The movement for a nationally supported system of experiment stations culminated in the Hatch Act of March 2, 1887. It authorized an annual appropriation of $15,000 for a station connected with each of the agricultural colleges established under the Land-Grant College Act of 1862. This gave a marked impetus to the experiment stations, and states which had not previously provided them promptly took advantage of the act. In 1906 the fund was supplemented by the Adams act, designed especially to promote original scientific research on agricultural problems. On its maturity in 1911 this act doubled the annual federal support. As the nature of the Adams fund required separate accounting, the project plan for experimentation came to be adopted generally at the stations.

Federal aid was again enlarged in 1925 by the Purnell act, which authorized an increase of $20,000 to each state the first year, with annual additions of $10,000 until $60,000 was reached. It also extended the research covered to include agricultural economics, home economics and rural sociology. By 1930 each state was receiving $90,000 of federal funds and providing an average of about three times as much for station work. The Bankhead-Jones Act of 1935 provided substantial funds for federal regional laboratories which co-operate closely with the state stations.

The state stations established experimental fields and trial grounds, accommodations for experimental animals, insectariums, creameries and cheese factories, veterinary hospitals, and laboratories for chemical, botanical and bacteriological research. They publish bulletins, circulars and annual reports containing the results of their work. Popular articles are prepared for the press, while the more technical features of research are published in appropriate scientific journals

The stations have close contact with the farming public and with extension workers The results of experiments are thus spread broadcast, often being applicable far beyond the states where the investigations were carried out.

The experiment stations in Alaska, Guam, Hawaii, Puerto Rico and the Virgin Islands are maintained under the federal department of agriculture with special congressional appropriations. Many of the states have branch stations dealing with special enterprises, such as citrus fruits, sugar, rice and tobacco or with the special problems of localities. There are also a number of special stations in the states without federal aid.

In addition, there are a number of privately supported centres like the Boyce Thompson Institute for Plant Research at Yonkers, N.Y., and the Marble laboratory at Canton, Pa., for the study of fruit storage.

**AGRICULTURE, CENSUS OF.** A national census is a periodic stocktaking or inventory of the population, material resources, production and social conditions of a country and its people. The early censuses were simple counts of population by age and sex mostly for political and military uses. In a modern census schedule, scarcely any subject about which a group may have developed an interest or curiosity is too particularized to find a place—such items, for example, as the number of deaths from cancer, the number of restaurants selling cigarettes and tobacco, and the state of repair of plumbing equipment in buildings. Or to cite items from agriculture, immigrant farm operators in Canada according to period of residence and farming experience, pounds of grain fed to fish in artificial ponds in Czechoslovakia, amount of peat used for litter on farms in Finland, or number of farm dwellings with running water in the United States. Censuses of agriculture, however, concern themselves especially with the number and size of farms or holdings, the uses of the land, the acreage and production of crops, the numbers of livestock and volume of livestock production, quantities of wood cut for various purposes, and the numbers and classes of farm workers. At least these were the subjects included in the First World Agricultural census, taken in 1930.

Supplementary subjects, to be included by those countries that could afford them, were farm tenure, farm machinery, use of fertilizers, nursery and greenhouse establishments, and irrigation and drainage.

**Purposes Served.**—A distinction is usually made between an agricultural census, taken perhaps at intervals of ten years, and the customary annual reports of acreage of crops, numbers of livestock, and crop and livestock production, summarized in the *International Yearbook of Agricultural Statistics* by the International Institute of Agriculture (*see* AGRICULTURAL STATISTICS) A census is likely to be more comprehensive and to include items in which changes from one year to the next are not very significant, or for which a full record over the years is not needed. Data on food production, for example, must be complete for successive years if they are to answer important questions on the food supply. If only decennial census data were available, the production of the intervening years would need to be interpolated.

The distinction between a census and an annual report, however, became less clear as more items were included in the annual inquiries. For many of the remaining items, new sampling procedures were developed to provide reasonably accurate statis-

tics at much lower cost. Thus a 5% sample of farms may furnish the facts needed as to the increase in electrical installations on farms, or introduction of a new variety of cotton, or change in the method of hiring labour or leasing systems. Some countries, like the U S.S.R., rely almost entirely on annual statistics If information on a particular subject is needed at any time it may be added to the next annual enquiry. Some countries, like Great Britain, were collecting annual statistics long before their first agricultural census. Great Britain took her first agricultural census in 1908, and her third in 1932 in connection with the first world agricultural census. The United States took its first agricultural census in 1850. A few of its annual series were begun in 1860.

It appears, therefore, that a census of agriculture does not stand by itself. It is only one part of the large undertaking of keeping a running inventory of the agriculture of a country and recording and measuring the changes in its structure, organization and social conditions. A census takes a somewhat detached cross section every ten years or so; and an annual enquiry a more frequent but less inclusive cross section. Certain other types of change, such as in livestock production, in condition of crops and pastures, in market receipts and prices, and in stocks on farms and in warehouses, need reporting monthly or oftener. All three of these types of enquiries fit together to give the full record Properly integrated, each also assists and strengthens the other. The census data become benchmarks against which the year-to-year changes are measured. Each new census provides a check on the accuracy of the annual estimates that have been projected forward from the last census. The annual reports similarly become benchmarks for the monthly reports. Data on market receipts provide checks on census data on production.

Since these three types of enquiries are so interrelated, it is important that they employ a common statistical language. This means using the same terminology, units, classification and area subdivisions. The data from any one of these sources need to be comparable with those from the other two. For example, the census should not assemble data on crop land sown and the annual enquiry report only crop land harvested. Hence, a country should either have only one statistical organization for assembling and compiling these three types of agricultural data, or it should give some unit of government the authority to co-ordinate the work of the separate organizations.

## THE WORLD AGRICULTURAL CENSUS

Agricultural statistics need to be comparable among countries as well as within a country. This need and that for a more complete coverage of the agriculture of the world, led to the attempt, under the leadership of the International Institute of Agriculture, to obtain a world agricultural census in 1930. The general assembly of the institute adopted a resolution to this effect in 1924. By 1928, a standard form or schedule of questions had been developed and approved by the general assembly. Committees of statisticians and agricultural economists from the countries adhering to the institute met at Rome in 1925, 1926 and 1928 and helped plan this enquiry. The Rockefeller foundation assisted with a five-year grant. Leon M. Estabrook, previously in charge of the crop and livestock reporting service of the United States department of agriculture, directed the institute's part of the work. In 1926–28, he visited 61 countries in order to interest them in taking part in the proposed census of 1930–31 and to discuss with the statistical authorities in these countries the details of the task of taking the census. As a result, 63 countries, out of a possible total of 200, participated either by carrying out a complete census, or to use the exact language of the census report (Vol. I, p. 71) "by making special inquiries or by attempting to obtain and furnish the Institute with information, for the census year, more complete and exact than normally available." These 63 countries included more than half the area and population of the world, and if China and the U.S.S.R. were excluded, about two-thirds of the remaining area. The list of 63 countries included 23 in Europe all of North America, 6 countries in Asia, 11 in Africa, 6 in Oceania, 5 in South America and 8 in Central America.

The individual countries handled the tabulation and compilation of the data of the census returns and in most cases published the results in their own principal language. The International Institute of Agriculture undertook to prepare summaries of the census reports of the individual countries as they became available, and to publish these summaries in English and French. In 1939, 39 of these summaries were assembled in Vol I to V as the *First World Agricultural Census*, together with "the standard form," a "methodological study" on the experience of taking this census, and "Notes on Tabulation of the Census Results" (in Vol I).

In the meantime, preparations were made for the second world agricultural census to be taken in 1940–41. The bureau of statistics of the institute prepared a revised standard form, and this was reviewed by a group of statistical experts from different countries in Oct. 1936. The revised standard form resulting was then sent out to all the nations for criticism and suggestions. The replies received were summarized in a pamphlet, "The World Agricultural Census of 1940, Documentation for the Second Conference on Agricultural Statistics" published in 1937. The second conference was held in Dec 1937 and the revised schedule was sent out in 1938. During World War II the staff of the institute summarized the census reports of the different countries as they became available. Part of them never became available because of the war.

The 1930 world census of agriculture made a special effort to collect useful data on the subject of labour employed in agriculture, because of the interest in this subject developed by the International Labour office. The 1940 census undertook to expand further this phase of the enquiry. The League of Nations also developed a strong interest in nutrition in the 1930s. Following a resolution introduced in 1935 by High Commissioner S. M. Bruce of Australia, a Mixed Committee on Nutrition of the League was appointed to consider the possibilities of relieving agriculture by getting its surpluses consumed by the world's underfed peoples. By 1938, national nutrition committees had been formed in 21 countries. This rapidly-growing interest in nutrition was recognized in the 1940 world agricultural census by an attempt to get a fuller reporting of all food production and especially of the production of milk and other foods of high nutritive value. The resolutions of the United Nations Conference on Food and Agriculture held at Hot Springs, Va., in May 1943 called for still more emphasis on collecting the data needed for a world program designed to place "adequate food . . . within the reach of all men in all lands within the shortest possible time," and the program for the international Food and Agricultural organization calls for developing more complete and accurate statistical information, and devising more effective methods of obtaining it.

## THE CONDUCT OF AN AGRICULTURAL CENSUS

Most persons who know about censuses at all think that there is only one way of conducting them—the way in which they are conducted in their own country. Actually the methods differ widely, usually for historical reasons. The original need for information determined the method which was followed after that. The original need may have been for a list of all the persons of age suitable for military duty, or for a listing of property for taxing purposes, or, as in the United States, for a count of the people in order to apportion them into voting districts.

**Methods of Collecting Data.**—The "Methodological study" Vol. I, p. 72, *The First World Agricultural Census* distinguishes between two major methods of collecting census data: making a record for each farm, and making estimates on the basis of data from existing sources or from samples. All but 17 of the 63 countries participating in the 1930 census used the first method. In 6 of these 17, France, Algeria, Peru, India, Japan and "probably El Salvador," the data were reported by communes or other administrative units. In making up the report for the commune, the local officials may have obtained some of the information directly from individual farmers, or may have depended in part on the annual data collected from individual farmers. The remaining 11 countries, all colonial, made approximate estimates by

combining the results of special surveys with pre-existing information.

The countries making a record for each individual farm may not have made an actual farm-to-farm canvass. Instead they may have filled in a schedule for each farm without visiting it by combining existing cadastral or other information for each farm with estimates of yields and crop acreages obtained from annual crop and livestock reports. Numbers of livestock for each farm may have been obtained in the same way or from tax records. Many countries making a farm-to-farm enumeration before 1930 had obtained data only on acreages of land and crops and numbers of livestock, and had compiled their production data by applying to these data average yields per acre or production per animal obtained from other sources. Most of these countries continued this practice in 1930, and the instructions for the 1940 census contain explicit directions for this as an alternative method of determining production.

The actual farm-to-farm enumeration may, in turn, be made in several ways. The method favoured by the International Institute of Agriculture is to have specially-trained enumerators obtain the information verbally; or to mail the schedule to the farmer to be filled in by him before the enumerator calls in person to collect it. In the latter case, the schedules need to be checked carefully before the enumerator leaves. In many countries, however, a local administrative official, or the rural police, distributes and assembles the schedules. This may result either in an incomplete census, or in one not very reliable because many schedules are completed in the office.

If special enumerators are employed, they need to be properly equipped and trained. In the United States and several other large countries, a new staff of enumerators is organized for each census; and under these circumstances very little of the training and experience gained in one census is carried over to the next. The best administrative setup is a regular staff which collects the annual as well as the periodic census data, and also helps with the monthly reports and the office work. This setup is easily arranged when all three types of agricultural statistics are collected by one organization.

**Date of the Census.**—The desire of the planners of the 1930 world census of agriculture was to obtain crop and production data for the calendar year 1929 in the northern hemisphere, and for the comparable year beginning July 1929 in the southern hemisphere; and to have a similar census taken each ten years thereafter. It was hoped that the different nations would shift the year of their enumeration to fit into this schedule, by 1940 if not for the first census, so that thenceforth the data would be comparable in time. Germany had taken an agricultural census for the crop year 1925 and waited until the crop year 1933 to take another. Sweden, Great Britain, Canada and four other countries were from one to three years late for similar reasons. The same difficulties arose in 1940. For example, Argentina and Chile had taken censuses in 1937 and were not able to repeat them.

The United States and a number of other countries take quinquennial as well as decennial censuses of agriculture. Great Britain made plans for this at the time of its census of 1908, but World War I interrupted the 1913 enumeration and the returns were never tabulated. The reason for shifting to a 5-year interval in the United States was that some of the annual estimates projected forward from the last census were proving to be seriously in error after seven or eight years.

The time of year for taking an agricultural census is also important. The best time for a census that includes production is after the principal crops are harvested and before the migratory workers and other operators customarily do their moving from farm to farm. This means November to January in the northern hemisphere. The countries which obtain only crop acreages and livestock numbers, however, are likely to prefer the summer months when livestock numbers are largest. The census officials of the United States asked that the date of enumeration be shifted from April to a winter month, but congress, after acceding to this request in 1920, refused to do so again for any decennial census—too much of the population gets counted in Florida or California in the wintertime.

**What Farms to Include.**—No problem in census taking has caused more difficulty or dispute than that of what types and sizes of rural establishments or holdings to consider as farms. Those which have looked at the problem from the point of view of classifying the population according to its major source of income have wanted to set a relatively high requirement. Those which have been concerned over obtaining a full enumeration of all agricultural production have wanted a very minimum limit. Most countries have a large number of very small farms, or of families producing small amounts of agricultural products for use of the family or for sale, or for both, and a slight change in the definition of a farm will change the count greatly. Part of these families have another principal occupation or source of income. Others have only very small incomes which are nearly all in the form of food and other products consumed directly by the family. Although the United States kept the same definition of a farm after 1910, changes in the instructions to the enumerators in 1930, 1935 and 1940 caused the number of farms to fall from 6,448,000 to 6,289,000 between 1920 and 1930, to rise to 6,812,000 in 1935, and to fall to 6,100,000 in 1940. In one eastern seaboard state, the number of farms reported almost doubled from 1930 to 1935.

The standard definition of a farm in the first world agricultural census was as follows.

"A farm, for census purposes, is all the land used wholly or partly for agricultural or live stock production, that is operated, directed, or managed by one person alone or with the assistance of others, without regard to ownership, title, size or location, and may be in one or more separate pieces if they are in the same neighbourhood and are known and operated as a single holding or property. The person who operates or directs the farm may be owner, tenant, hired manager, or one who holds or controls the land and its products under a special form of tenure . . . The farm may be known as a lot, piece, or parcel of land, garden, orchard, estate, ranch, plantation, rural establishment, proprietorship, or other name, but in any case must be operated, directed or managed by one person. Woodland and forest land that forms a part of the farm or holding and is controlled, directed or managed by the farm operator will also be reported as well as the plots of ground and buildings occupied and utilized by the laborers employed and living on the farm."

Thus no common lower limit was placed on size. The Netherlands and Austria, at one extreme, set the limit at one-eighth of an acre; the United States, at the other extreme, at three acres, or less if the value of the product was $250. In Great Britain and the empire countries, the limit was commonly one acre. In Northern Ireland however it was one-fourth of an acre, as also in Eire; and in the Union of South Africa, one morgen (2.1 ac.). The other continental European countries set limits ranging from a quarter of a hectare (in Finland), to a half-hectare (Germany and Belgium), to one hectare in Latvia, Estonia and Lithuania. (Hectare=2.47 ac.) These Baltic countries, however, had a special schedule for establishments of less than a hectare.

Qualitative differences also enter into the problem of what constitutes a farm. In some countries, kitchen gardens and backyard poultry flocks on land adjoining a non-farm dwelling are not included as farms. In Switzerland the question is whether or not any of the product is sold. In New Zealand such production is excluded if it is within borough boundaries; in Italy, if it is in cities of 15,000 or more inhabitants. Practice also varies with respect to livestock not on farms.

Much confusion also arose in the first census over considering separate units under one landlord as all one farm, or each unit as a farm. In France, the practice was to call them one farm. The general rule which the census makers would like to apply is that any land under a *single management* should be considered a farm. But share-croppers contribute only part of the management, in many situations less than half of it. Italy and Yugoslavia met this problem by having a supplementary schedule for central managements. The United States used a supplementary "plantation" schedule in its 1940 enumeration. The 1940 world agriculture census tried to meet this difficulty in part by using the terminology "farm or holding" in place of "farm." But in some countries, any parcel of land is called a holding whether or not it is independently operated. Also in the countries of central Europe, where much land is operated under managers, one overseer may look after several holdings.

It follows from the foregoing that the census totals on number of farms and farm operators for the various countries are far from being comparable; yet these are among the most significant measures of agricultural change. This difficulty will not be overcome until the enumerators are required to return a schedule for all agricultural production down to a very low minimum, and the final classifying is done in the office subsequently. One cannot expect enumerators to apply uniformly an involved census definition like that for a farm or holding.

**Tabulation of the Returns.**—Before tabulation can begin, the returned census schedules must be edited. This involves checking the figures on each schedule for internal consistency and comparability with other returns, and perhaps a good deal of filling in of gaps in the schedules. Practice varies as to the extent of the latter. If the gaps are not filled in, either the farms with partial returns must be omitted or the published tables must report for each item the number of farms with no reports, letting the user of the tables do his own estimating if he wishes. Most statistical offices follow a combination of all three of these procedures, the choice in each case depending upon which introduces the least error. For example, the debt status of farms with

no report on mortgage debt cannot safely be estimated, whereas production frequently can.

The comparability of the census data of different countries may be improved greatly if a uniform classification of farms and land by size can be applied in the tabulation process, and ... according to use, livestock according to age, farm ... to age and employment, etc. The planners of the two world agricultural censuses gave much attention to developing such classifications and the data published in Vol. II to V show the effects of this.

## SUBJECTS OF CENSUS ENQUIRY

The conduct of an agricultural census, even in any one country, in such a way as to obtain data that are comparable from one enumeration to the next and from one region or province to another is an unusually difficult undertaking. Adding comparability by countries makes the task seem imponderable. The world was not made to fit the requirements of simple and accurate census taking. Rather, a census must adapt its methods to the infinite variety and complexity that man has introduced into a physical environment already diverse enough in itself. In the sections following, these adaptations will be considered according to the main subjects included in the two world agricultural censuses of 1930 and 1940.

**Farm Labour.**—In spite of the growing interest in farm labour, only questions relating to "permanently employed" workers were considered safe to include generally in the 1930 census. The questions included age over or under 15, sex, and whether or not members of the farm family. Even then, only 35 of the 63 countries included these questions in their enquiries. Similar questions as to temporarily employed workers on the date of the census were included under the supplementary questions, also questions as to number of days worked, wages, housing and hours worked per day. Only 14 countries, however, included any of these questions in their schedules. Some of the 35 countries attempted to classify farm labour in other ways than suggested in ... form, using such designations as administrative staff, overseers, foremen, farm servants, artisans, shepherds, cowmen, ploughmen and vine workers. The farm labour part of the standard form was discussed at length in planning the 1940 census. The principal change was to define the term "permanently employed" to mean employed during a crop season only, or regularly over the year. In both censuses, the countries were also asked to report the particular employment conditions on the date of the census, and something about number employed at other seasons.

**Land Use.**—Since land is the basis of all agriculture, the most important classification in any agricultural census is that of its lands by major uses. A major problem is that of classifying lands that have mixed use as pasture and woodland. The United States census uses the designation "woodland pasture" for such lands. The world census calls for classifying it either as woodland or as permanent pasture or meadow—according to which is the more important use. This is a definite advantage in case one wishes to work out ratios of farm population, workers or animal units to agricultural land; or analogous ratios for woodland and forest.

A similar problem is that of classifying land once tilled but in pasture or meadow for some years past. If it is to continue in grass, it should no longer be called arable. In England and Wales at one period, much of such land was kept in the arable class for a decade or more after it had ceased to rotate from tilled crop to grass. The standard form calls for classifying such land as arable for only four years after its last ploughing and as permanent meadow or pasture after it has been in ... years. This is too short a period for some of the rotations in which alfalfa and similar forage crops are grown; but apparently the world census planners assume that land in grass for five years or more in a ... hay most of the time, and hence is more properly classed as meadow than as arable. The term arable, it must be kept in mind, means ploughed or tilled, not tillable or cultivable.

In intensively-farmed countries like those of southern Europe, one finds much intermingling also of tilled crops and fruit or nut trees or bushes—"two-story agriculture." In this case, the world census asked to have the division of the area estimated, and if this was not possible, that it be classified according to its chief object.

The remaining land-use classes in the world census are "productive marshlands, heathlands and other productive but uncultivated lands," and "unproductive lands." The first of these seems precisely to take care of a good deal of land that was never "improved" but furnishes grazing, wild hay, berries and other ... fruits.

Seventeen countries adopted the ... as outlined, and ... adopted it with modifications. The principal variations were those found in the censuses of the United Kingdom, Denmark, Norway and India, in which "cultivated land," or "land in crops and grass" were not reported into arable, permanent meadow and grass, and trees and shrubs, and that of the United States and Australia, in which cropland and pasture are the two sub-classes, and trees and shrubs are included in cropland.

**Crops.**—The classification of crops outlined for the 1930 census was as follows: cereals harvested for grain, legumes for grain, tuber and root crops for food or forage, cultivated hay and forage crops (that is, grown in a rotation system), crops for industrial use, vegetables, crops grown for seed, crops sown but not harvested in the year of the census, fallow land, permanent meadow and grass, vineyards, ... orchard fruits and nuts, small fruits, and miscellaneous ... (including coffee, tea, cacao, pepper, chinchona, rubber, ..., sago palms, etc.). Under these heads, more than 100 different species of plants were listed, and others were provided for under such headings as "other vegetables," "other fruits and nuts." A major ... introduced by the growing of two or more crops in the ... one year, or ... two crops on the same land at the same time. The ... were, in the first case, to enter the areas of the later crops in brackets on the same line, and in the second, to divide the acreage if possible, and, if not, to list the combinations on separate lines.

Needless to state, the various countries introduced a great many variations on their schedules. Most of them, however, were details under the headings named. For example, 36 vegetables were listed separately in one country or another, in addition to the 9 in the standard form, and 8 tuber or root crops in addition to the 9 in the standard form.

**Livestock.**—Nine species of livestock, including bees, were listed in the general form, and 10 more in the supplementary questions (including camels, llamas, reindeer, ..., buffaloes, ostriches, foxes, skunks and rabbits). The principle ... was that of age classification. The general system adopted was that of one class to include animals born recently enough so that they measure the reproduction of the year past, or the last gestation period—like calves under 1 year, and pigs under 6 months, another class for female breeding stock, and another for male breeding stock. For poultry, only total numbers were asked for. Most of the countries adopted this system of classification, but some of them introduced more detail. For example, 26 of them, including the United Kingdom and the United States, listed cattle 1 to 2 years separately, and 16 of them listed ... chickens separately. It was apparent that even with these age ... the difficulty introduced by taking the census at different times of the year in the different countries was met only in part. Supplementary estimates of maximum and minimum would help, but were difficult to obtain.

**Production.**—The standard form in both world censuses asked for quantity produced as well as acres of crops and livestock numbers. Half of the purposes which agricultural statistics serve require data on production. Nevertheless, only 31 of the 46 countries reported production of annual crops, and fewer reported production of orchard fruits. Only 29 reported production of milk, butter and cheese, and 21 the production of eggs. These results followed even though the alternative procedure was allowed if necessary of estimating production by multiplying acres and numbers of productive livestock by yields per acre and per animal. Clearly the international Food and Agriculture Organization has a large task ahead before it will be able to measure the food supply and nutrition levels of large sectors of the world's population.

**Other Subjects.**—Of the remaining subjects covered in the supplementary questions, farm machinery called forth the largest response. Not only did more than 30 countries collect data on the six types of machines named in the schedule, but many of them listed additional types or subtypes—for example, nine kinds of power machines. Only a limited number supplied data on the acreage of land drained or irrigated, but most of these included additional details. Most of the countries limited their census of woodland to land within agricultural holdings. Nine, however, all but one in Europe also included independent forest holdings. Also eight countries followed the standard form in asking for a report on woods cut every few years, usually referred to as coppice in the enquiries. Only 15 asked for a report on the quantity of wood cut for fuel, pulp and other purposes. Finally, five European countries collected data on the total area of ponds stocked with fish and fish production.

Tenure systems are exceedingly varied, and the attempt in the supplementary questions to fit all farm land into the categories of owner-operated, cash-rented, share-rented and managed was not very successful, only 19 following the schedule outlined.

It would be a serious error to adjudge the scope of agricultural censuses by the subjects considered wise to include in world censuses. Other important subjects included in some enquiries are farm buildings and transport and communication; farm population: age, nationality and race of the farm operator; value of farm property, value of products raised or sold, farm expenses, farm income, farm debt and membership in farm co-operatives. The United States, France and some of the British dominions took the lead in expanding the census to include economic and other social information.

It would also be a serious mistake to judge the adequacy of world statistics on agriculture by the contributions of the 63 countries to the first world census. First of all, several countries, like the U.S.S.R., had other methods for keeping a running inventory of agriculture. Second, a considerable list of countries had taken censuses of a sort one time or another, but could not arrange to take one in 1930. Finally, most countries have official statistics or records that furnish a rough measure of agricultural developments.

Most agricultural censuses begin with a simple counting of farms, livestock and acres in different crops. A majority of the censuses of agriculture by the time of World War II were still in this counting

stage. While still in this stage, however, the number of items can be expanded considerably to include land use, workers, farm machinery, and more details as to crops and livestock The second stage of development is the inclusion of data on production The third step adds values and prices to the crop and livestock production, and to farm equipment and livestock If farm expenditures are then added, it becomes possible to estimate the gross value of agricultural production, and gross and net farm income, which can be included in estimates of the national income. Only a limited number of countries had reached this stage by 1944.

(For agricultural statistics of various countries, *see* the individual articles on those countries; likewise for states, provinces and other geographical divisions; *see* also AGRICULTURAL STATISTICS) (J. D BL)

**AGRICULTURE, CHAMBERS OF.** The Central Chamber of Agriculture in Great Britain was founded in 1866 simultaneously with the formation of local chambers in the country. These were combined into one association, known as the Central and Associated Chambers of Agriculture. The objects of the Association are to promote the interests of agriculture, and with that view to watch over all measures affecting agriculture both in and out of parliament, and to take such action thereon as may seem desirable in its interests. The scope of the association has widened, and it now comprises not only chambers and farmers' clubs, but agricultural societies, unions, federations, dairy associations and other agricultural institutions. Its aim is to form a common centre for all the different sections and groups in the industry. The work of the chamber is governed by a council of twenty-four members chosen by the subscribing members of the central chamber, and about 70 deputies appointed annually by the various federated bodies.

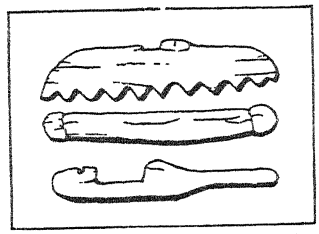
**AGRICULTURE, PRIMITIVE.** Agriculture (cultivation or tillage of the ground for the production of plants for food) is the basis of civilization, and primitive agriculture marks the transition from the lowest cultural stage, commonly called savagery. When and where, how and why were the first steps taken? No simple answer can be given. As to the date and place, a few hints are given by archaeology, but where primitive agriculture is now established there is rarely even a tradition of its origin. "God Almightie first planted a garden" is the general belief, God being represented by Osiris in Egypt, King Kintu in Uganda, Sidi or Soidi in Torres Strait, Ofanu in Tahiti, Tupan in Brazil, and by all the other local culture-heroes who brought the good gifts to men. As to the how and the why, information must be sought in areas where beginnings are being made.

There is as yet no cultivation of the soil or raising of crops in the Arctic regions, in the semi-desert regions of north and south Africa and Arabia, the high plateaux of Tibet and Mongolia, or the whole of central Australia. It is unknown also in certain jungle areas inhabited by groups of pygmy peoples, such as the Negrilloes of the Congo, the Andamanese, the Semang of the Malay peninsula, and there is no record of it among the extinct Tasmanians.

AN EGYPTIAN HOE FOUND AT THEBES USED IN THE NILE VALLEY ABOUT 2,000 B.C.

The first steps have been noted in various parts of the world. In Western Australia a species of flag was cultivated to the extent of burning down the crop at the end of the season to improve the next crop. Also, when digging up yams, the natives replaced the heads in the holes. Purslane (*Portulaca*) was also encouraged if not artificially cultivated. The Besisi of the Malay peninsula used to carry fruit they were eating to fresh spots so that the seeds might spread over the country. In Arizona a company of Cocopa, Mohave or Pima women, safely guarded by a number of men, set forth to a rich and favourable spot on the side of a cañon. Each woman has a little bag of gourd seed, and she plants these, one by one, in rich crannies or crevices where the roots can find sustenance, the sun may shine in, and the fruit may later swing down, as from a trellis. The planters go home and take no further notice of their vines until they return in the autumn to collect the gourds In manioc areas, the natural means of procuring food is still by hunting. Cassava forms a useful alternative, and when game is scarce or hunting unsuccessful, manioc culture increases in importance, yams, beans, peas, pumpkins and maize being added to the crops, while if hunting fails altogether, the group perforce turns to agriculture. Examples are common in the Congo region Similarly compulsion turns pastors into agriculturalists. In Africa the women have no share in cattle tending and are often mainly occupied in cultivating the crops of maize and vegetables. Should war or disease cause the herds to dwindle, or encroachments diminish the extent of the pasturage, the necessity for agriculture is increased until it absorbs the whole community. Sometimes the stimulus is given by political pressure, as in the case of the Bashkir Tatars, whose pasture lands were encroached upon by Russians to the north and west, and by the Ural Cossacks to the east, so that they could no longer support flocks and herds in sufficient numbers. Sometimes, however, although the first steps are taken, progress goes no farther, as in the wild rice districts of North America in the neighbourhood of the Great Lakes. Most of the Indians who had access to the rice fields collected the rice, ate it at every meal until it was finished, and then turned to other sources of food. There was a common belief that if any seed were sown no more would ever grow wild, and while food was plentiful and space and game were abundant, no further steps were taken.

**Assartage.**—In tropical or semi-tropical countries the common method of agriculture is assartage or essartage (from Lat. *exsartare*, to grub up trees and bushes from forest land to make it arable). For example, in South America a tract of specially productive forest land is chosen as a site for a maize field, smaller trees and undergrowth are cut down at the end of the rainy season, except those of greater size or of very hard wood, and the fallen masses, dried by sun and air for a few weeks, are then fired. On this charred surface, among half-burnt branches and blackened trunks, the maize is planted in holes a few feet apart and when it reaches the surface the Indian clears and stirs the ground with the hoe. Immediately after harvest the ground is prepared for a fresh crop, which, however, yields much less, and the clearing is then abandoned for several years. It soon becomes overgrown with weeds and undergrowth, and after a time, if no virgin land can be had, these will be burnt down and the land replanted as before; but the crops are poor, the soil is exhausted, the ashes of the undergrowth have not sufficient fertilizing value, and the clearing is finally abandoned. The burning of the felled trees enriches the land, and the same clearing can be used two, three or more times, but is less and less productive each season, so that new land is prepared and the cropped piece left fallow. The system is practised wherever space permits.



In Torres Strait each family has its patch of garden land marked out within the tribal area by definite boundaries. The limit may be marked by standing trees but more commonly the boundary is a ridge of earth, formed by the weeds and refuse thrown on the edge in the process of clearing the land. Every year a man clears a new piece of land and lets another portion lie fallow. The men cut down the larger trees, formerly with shell axes, while the women attack the undergrowth. There is no regular rotation of crops; usually the same plants (yams, bananas, sweet potatoes or sugar-cane) are planted in the same patch; only, as the crops deteriorate after one, two or three years, the land is allowed to lie fallow until the undergrowth is four or five years old, when it is cleared again. There are special names for gardens of successive ages. A newly cleared patch is *kerkar gedub* (new garden), next year it is *keas gedub*, and after two years *gazag gedub*. *Keas* and *gazag* gardens are not replanted, though sugar-cane and bananas continue to bear. (Torres Strait Reports, iv. 145–151.) Extensive agriculture (clearing a fresh patch every season) may go on as long as there is sufficient land, either virgin land still uncleared or overgrown fallow worth clearing; but where, owing to limitations of land or increase of population or

other economic influences, more crops or better crops are required and the exhausted land cannot restore itself, artificial restoration must be applied. Extensive agriculture becomes intensive.

Agriculture is everywhere associated with magic and religious ceremonies to ensure fertility, but artificial fertilization of a more practical nature is not unknown to primitive gardeners Mariner describes it in Tonga in 1827; powdered pumice was used in the Gilbert isles; human manure was a marketable commodity in Mexico, as in China In America artificial manuring was found from Nova Scotia to Chile. Fish was commonly planted in the maize hills with the seed and guano was carefully collected. In Peru extensive cultivation was impossible from lack of space, and crops were restricted to the pockets (*bolson*) of rich soil, formed from detritus washed down by the mountain torrents, enriched with mineral deposits from volcanic rocks. These natural plots were enlarged by irrigation streams which were also fertilizing. The guano beds of Peru were highly valued; they were the property of the different provinces, and the breeding places of the birds were protected by law.

**Irrigation.**—Leading an artificial stream on to a patch of land, to provide water for a crop varies from the hollowed tree-fern trunk which the Fijian lays down to supply his taro bed, to the imposing engineering works of the primitive agriculturalists of Peru, or the miles of aqueducts of ancient Ceylon. The sources of water may be natural rivers or lakes, artificial canals, reservoirs or underground supplies, and there are many contrivances for directing it over the land to be watered. Water from a higher level is led off in narrow mud-banked channels which can be stopped or diverted merely by blocking up or breaking down a channel wall here and there. If the water has to be raised, a man may sit by the side of a stream with a half gourd or coco-nut (now-a-days often a kerosene tin) fixed to a stick, ladling out the water and pouring it on to his crop. In deep water a bucket is lowered by means of a rope and drawn up to the surface. The *shaduf*, characteristic of Egypt, and widely distributed from West Africa to the East Indies, consists of a forked pole stuck in the ground, with a long pole balancing on the fork, its heavier end on the bank, and the lighter end, with a bucket attached, over the water. The bucket is lowered into the water, and, when full, the heavy end of the pole helps to raise it. Water can thus be raised 10 or 15ft., and a succession of *shadufs* can raise it to any height required. When there is running water, a water-wheel with buckets on an endless chain is common in the Old World, or the wheel may be turned by animals or men. Where the underground supply of water is very deep, as in parts of India or in the Sahara, a pit is dug, walled in with masonry, and a skin bag lowered over a pulley by long ropes to a depth of 100 or 200ft. The ends of the ropes are attached to bullocks, mules, donkeys, camels, women or slaves, who walk down a slope equal to the depth of the wall. Neither the *shaduf*, the water-wheel or the pulley was used in the New World, but there are extensive irrigation works in the drier Pueblo region, especially Arizona, where 150 miles of ancient irrigation ditches may be traced. In Mexico and Peru extensive engineering works prove the care given to irrigation. Channels were carried round the sides of mountains and even tunnelled through them; so that the waters of the higher valleys where the supply was abundant were made available for the cultivation of others where it was deficient; and these channels were made to irrigate not only the cultivated fields but the llama pastures on the mountain sides.

**Terrace Cultivation.**—In clearing sloping land for planting, trees are felled, stones are collected or undergrowth and weeds heaped up all along the edges of the space to be planted, and ridges and terraces are thus formed. The discovery of their value for preserving moisture and preventing erosion on slopes would easily lead to the artificial terracing so widely distributed throughout the Old and New Worlds. Terrace cultivation is imposed on agriculture by political, geographical, climatic or economic influences. An agricultural group is by its nature exposed to attacks which, by its nature, it is unable to resist except by retreat to a naturally fortified or easily defended position; and this is provided by the hills, where every patch must be carefully preserved and augmented. Artificial banks are therefore raised to prevent further erosion, and, if necessary, loads of earth are retrieved from the valleys Such is the precarious agriculture of the Man Tze, or "untameable worms," as the aboriginal inhabitants are called by their Mongol [illegible] who forced them to retreat into the mountain fastnesses of the Yangtse valley, where, at a height of about 10,000ft. above sea-level, they perch their villages on the steep cliffs. The back of the house is burrowed out of the rock face, the front is supported on a platform, resting on beams; the approach is by steps made of bolts driven into the rock, and small children are tethered to the door-posts to prevent them from falling over the edge. Here in little patches between the rocks every inch of soil is carefully tilled and crops are raised though the only access to the terrace may be by a rope (I. B Bishop, *The Yangtse Valley and Beyond*, 1900) Both archaeology and history show evidence of early terracing round the Mediterranean and in Britain during the Bronze Age

A PRIMITIVE EGYPTIAN RAKE OF THE XXth DYNASTY FOUND AT LISHT

In hilly and mountainous districts where the rainfall is insufficient or irregular, terrace cultivation and irrigation go hand in hand The water from a mountain stream is easily directed down the slope, and the embankments of the terraces preserve the moisture, so this method is universal on the drier slopes throughout the world The Arabs in Yemen give the best example Here the mountains are terraced from their base up to sometimes as high as 6,000ft , with terrace walls from 5ft. to 15ft. high. Reservoirs filled in the two rainy seasons supply the streams for the irrigation channels. When, in the 10th century, the Arabs reached Spain, they converted every mountain slope into a succession of green terraces. In the mountain areas of India, in Ceylon, in Tibet and in China, terrace cultivation can be seen on a large scale. The Chinese, farmers of 40 centuries, carry terracing to a fine art. In densely populated neighbourhoods every inch of soil is of value; it is collected in baskets in the valleys, carried up the barren hill slopes, and embanked, forming astonishingly productive gardens. Examples are rare in the New World, but in Peru the same necessities were met by the same device, and hundreds of terraces one above the other rose from the valleys to the utmost cultivable limit. These were extended year by year by communal labour, and produced the finest crops of potatoes and maize, eliciting the astonished admiration of Cortes: "There was not a span that was not cultivated" Increase of population and of civilized wants, with the growing importance of food-crops or drink-crops, lead to the intensive cultivation seen in the mountain zone of Europe; in Switzerland, for example, or the Moselle and Rhine valleys, in the Vosges and Black Forest, in the Suabian Jura, in Italy, up the slopes of the Apennines or the Ligurian Alps, and in the "desperate agriculture" of Teneriffe, where camels laden with earth bring soil for the gardens almost daily into the town of Santa Cruz.

**Implements.**—The primitive implement is everywhere the digging stick, usually merely a strong stick, with one end pointed or flattened (a rudimentary spade) and often hardened in the fire. This is used for digging up roots by people who do not cultivate the soil, such as the Australians or the Bushmen of South Africa. The Bushmen weight their digging sticks with a heavy perforated stone whorl which acts as a lever. The digging stick or *ô* in use in Tahiti nearly a century ago was originally a stick sharpened at the point and hardened by charring at the end; but when iron was obtained, a narrow sharp piece like a chisel was fixed at the end, and as much of the ground was stony, this was found very convenient. No use was made of the foot in thrusting the spade into the soil, but the digger assumed a crouching attitude, piercing the ground and breaking up the earth by the strength of hands and arms (Ellis, *Polynesian Researches*, p. 137–138). In Fiji the grass, reeds and undergrowth were broken down by a sharp-edged club. The digging sticks (poles with one end flattened) are used by three or four men encircling a large clod which they lever up. The women, fol-

lowing on their knees, pulverize this with their hands. A hoe, made of turtle shell or an oyster valve, was used for weeding. A knife has now replaced the club, but as a spade is painful to bare feet, the digging stick holds its place, though its power is now increased by an iron blade. In New Zealand the Maori lashed on a foot-piece at right angles to the digging stick; in Peru a foot-rest is bound on with leathern thongs, and, higher up, another rest is attached in the same way; this is for the left hand, which assists the foot in applying the weight of the body to the thrust. Similar types are found from New Mexico to Chile. The *caschrom,* still used in the stony patches of the Shetlands and the Hebrides, is a larger and more elaborate digging stick, with its end shod in iron and a foot-rest attached. The hoe is really a pick, with the digging end flattened. The simplest form is a piece of wood, with a natural angle, usually part of the trunk and a projecting branch, or two pieces of wood fastened together. The former is illustrated in Europe in the Swedish "hack" and the latter was characteristic of ancient Egypt. In North America a bent piece of wood, the shoulder blade of elk or bison, or a piece of tortoise shell is fastened to a handle, but the hoe was rare in America except in the eastern maize area. African hoes are of iron, often set at an acute angle to the shaft, this and the shortness of the handle necessitating a crouching position when hoeing. The size and shape of hoes in Nigeria reflect the variation of soil, a gradation being traced from the sandy soils of the north to the heavier land of the south. There is little doubt that women were the earliest agriculturists. Even when the harder labour of clearing the ground is done by men, planting, sowing, tending and collecting are women's work. "When the women plant maize," said the Indians, "the stalk produces two or three ears. Why? Because women know how to produce children. They only know how to plant corn to ensure its [illegible] Then let them plant it. They know more than we do" (J. P. Acosta, *History of the New World,* ii, 7.) The fact that the cereal deities of the old and new worlds were usually female strengthens the view that the cultivation of plants is one of women's contributions to civilization.

**AGRICULTURE, TROPICAL:** *see* TROPICAL AGRICULTURE.

**AGRI DECUMATES,** "tithe lands" given by the Romans to Gallic settlers, and also to Roman veterans on the payment of a rent of a tenth (*decuma*) of the produce, on the east of the Rhine. (*See* LIMES GERMANICUS.)

**AGRIGENTUM** (Gr. Ἀκράγας, mod. AGRIGENTO), ancient city, south coast of Sicily, 2½m. from the sea. Founded by Greek colonists from Gela as late as 582 B.C., its favourable site for cultivation and trade with Carthage made it second only to Syracuse. Pindar calls it καλλίστα βροτεᾶν πολίων (fairest of mortal cities). Ruled at first by tyrants, in 472 a democracy was established. In the struggle between Syracuse and Athens (415–413) the city remained neutral. Its prosperity continued to increase (its population is given at over 200,000) until in 405 B.C. it was captured and plundered by the Carthaginians, a blow from which it never entirely recovered. It was colonized by Timoleon in 338 B.C. with settlers from Velia in Lucania, and in the time of the tyrant Phintias (289–279) it had regained some of its power. In the first Punic War, however, it was sacked by the Romans (261) and the Carthaginians (255), and finally in the second Punic War by the Romans (210). Still in the Roman period, it exported agricultural products, textile fabrics and sulphur. In the local museum are tiles used for stamping cakes of sulphur, which show that the mines, at any rate from the 3rd century A.D., were imperial property leased to contractors. The site is unusual and beautiful with a lofty ridge with two summits to the north. On the western summit is the modern town (985ft.), the eastern summit slightly higher, bears the name of Rock of Athena, owing to its identification by some scholars with the acropolis of Acragas as described by Polybius, who places upon it the temple of Zeus Atabyrius (said to have been erected by the half-mythical Phalaris) and that of Athena. The available space about 70 x 20 yds.) on the eastern summit is, however, too small. In the modern town, on the other hand, the remains of one temple are to be seen in the church of Sta. Maria dei Greci, while the other is generally supposed to have occupied the site of the cathedral. On the north both summits are defended by cliffs, on the south the ground slopes away somewhat abruptly from the eastern summit towards the plateau on which the town stood, while the western summit is separated from this plateau by a valley traversed by a branch of the Hypsas (mod *Drago*), the deep ravine of which forms the western boundary and defence of the city. On the east is the valley of the Acragas (Fiume S. Biagio). The church of S. Biagio, above it, is built into the temple of Demeter which was preceded by a sanctuary in the cliffs. The Acragas defends the approach from the east and the deeper Hypsas that from the south-west. They unite south of the town and flow out in the small abandoned harbour. A row of important Doric temples crowns the southern slopes; they are built of the local porous stone, which is of a warm red brown colour, full of fossil shells and easily corroded when exposed to the air. Of all these temples the oldest is probably that of Heracles (eight columns of which have recently been re-erected)

*Dimensions in English feet.

while the best preserved are those wrongly attributed to Hera and Concordia, which are very similar in dimensions; the latter, indeed, lacks nothing but its roof, owing its preservation to its conversion into a church in 597 by Gregory II., bishop of Girgenti. These temples are among the finest in existence In front of the former, as in front of those of Heracles and Zeus, stood a huge altar for burnt offerings, as long as the façade of the temple itself. The *cella* of the temple of Heracles was modified in Roman times, and a statue of Asclepius seems to show change of cult.

In the colossal temple of Zeus the huge Atlantes (figures of Atlas), 25ft. in height, are noticeable. They seem to have stood in the inter-columniations half-way up the outside wall and to have supported the epistyle. The collapse both of this temple and of that of Heracles must be attributed to an earthquake; many fallen blocks of the former were removed in 1756 for the construction of the harbour of Porto Empedocle. The four columns

THE TEMPLE HERE SHOWN WITH ALL ITS COLUMNS STILL IN SITU, WHICH HAS BEEN WRONGLY ATTRIBUTED TO CONCORDIA, IS THE BEST PRESERVED OF THE NUMEROUS AND SPLENDID RUINS STILL TO BE FOUND ON THE SITE OF THE CITY OF AGRIGENTUM. IT OWES ITS PRESERVATION TO GREGORY II. BISHOP OF GIRGENTI

erected on the site of the temple of Castor and Pollux are a modern (and incorrect) restoration in which portions of two buildings have been used. Of that of Hephaestus only two columns remain, while that of Asclepius, a mile to the south of the town, an anta and two pillars are preserved. Other remains are unimportant. Near the picturesque church of S. Nicolo is the so-called oratory of Phalaris, a tomb of the 1st century B.C., 27¼ft. by 23⅓ft., and not far off on the east are two private houses of the Roman period. The fishpond (circumference said by Diodorus to be 7 stadia) is an enormous excavation south-west of the city, with drains in its sides; the bottom is now an orange garden.

The wall line can be traced, but actual remains are small except in the valley below the temple of Demeter (S. Biagio). East and west ravines gave protection, so a massive wall was unnecessary, while near the south-east angle a breastwork was formed by the excavation of the natural rock, in later times honeycombed with tombs Close to this temple on the west is the site of the gate known in later times as the *Porta Aurea*, through which the modern road passes.

Tombs of the Greek period have been found mainly on the west of the town, outside the probable line of the walls, between the Hypsas and a small tributary, the latter having been spanned by a bridge, now called *Ponte dei Morti*, of which one massive pier, 45ft. in width, still exists. Just inside the south wall is a Christian catacomb, and outside it a tomb in two storeys, a mixture of Doric and Ionic architecture, belonging probably to the 2nd century B.C. A village of the Byzantine period has been explored at Balatizzo, immediately to the south of the modern town. The walls of the dwellings are entirely cut out of the natural rock.

The modern town, known as Girgenti till 1928 but then reverting to the older form of Agrigento, is the capital of the province of Agrigento, and an episcopal see, 58 mi. S by E. of Palermo direct and 84½ mi. by rail. Pop. (1936) 27,785 (town), 32,951 (commune). The cathedral occupies the highest point in the town; it was founded in the 13th century and there are other remains of architecture of this period. The museum contains fine vases, terra cottas, sculptures, etc. Porto Empedocle, pop. (1936), 13,834 (town), 14,764 (commune), 5½ mi. S. by rail, is connected with Castelvetrano, on the line from Palermo to Trapani. It is the principal port for the shipment of sulphur, the mining district lying just north of Agrigento, and was heavily bombed by the Allies during World War II after their victory in North Africa. (T. A.; X.)

**AGRIMONY,** a slender perennial herb (botanical name, *Agrimonia Eupatoria*, family Rosaceae), 1½ to 3 ft. high growing in hedge-banks, copses and borders of fields. The leafy stem ends in spikes of small yellow flowers. The flower-stalk becomes recurved in the fruiting stage, and the fruit bears a number of hooks which enable it to cling to rough objects, such as the coat of an animal, thus ensuring distribution of the seed. The plant is common in Britain and widely spread through the north temperate region. The underground woody stem is astringent and yields a yellow dye.

The name has been unsystematically given to several other plants; for instance: bastard, Dutch, hemp or water agrimony (*Eupatorium cannabinum*); noble or three-leaved agrimony (*Anemone Hepatica*); water agrimony (*Bidens*); and wild agrimony (*Potentilla Anserina*).

**AGRIOLOGY** is the science of the prehistoric human practices and ways of living, especially those pertaining to the key-factors of existence, food, shelter and clothing.

**AGRIONIA,** an ancient Greek festival, celebrated annually at Orchomenus in Boeotia and elsewhere, in honour of Dionysus Agrionius ("the wild") by women and priests at night. The tradition is that the daughters of Minyas, king of Orchomenus, having despised the rites of the god, were seized with frenzy and ate the flesh of one of their children. At this festival it was originally the custom for the priest of the god to pursue a woman of the Minyan family with a drawn sword and kill her. (Plutarch, *Quaest. Rom.* cii, *Quaest. Graecae,* xxxviii.)

**AGRIPPA,** a sceptical philosopher, whose date cannot be accurately determined. He must have lived later than Aenesidemus. To him are ascribed the five tropes (*πέντε τρόποι*) which, according to Sextus Empiricus, summarize the attitude of the later ancient sceptics. (1) Since some thinkers hold that nothing is known but the sensible; others that nothing is known but the intelligible, it follows that the only wise course is neither to affirm nor to deny. (2) The proof of one so-called fact depends on another fact which itself needs demonstration, and so on *ad infinitum.* (3) The data of sense are relative to the sentient being, those of reason to the intelligent mind; that in different conditions things themselves are seen or thought to be different. Where, then, is the absolute criterion? (4) All knowledge depends on certain hypotheses, or facts taken for granted. Such knowledge is hypothetical. (5) The fifth trope points out the impossibility of proving the sensible by the intelligible inasmuch as it remains to establish the intelligible in its turn by the sensible. Such a process is a vicious circle and has no logical validity. A comparison of these tropes with the ten tropes enumerated in the article AENESIDEMUS shows that scepticism has made an advance into the more abstruse questions of metaphysics. The first and the third include all the ideas expressed in the ten tropes, and the other three systematize the more profound difficulties which new thinkers had developed.

*See* Diogenes Laertius x. 88, and Zeller's *Greek Philosophy.* Also the articles SCEPTICISM, AENESIDEMUS.

**AGRIPPA, HEROD I.** (*c.* 10 B.C.–A D. 44), king of Judaea, the son of Aristobulus and Berenice, and grandson of Herod the Great, was born about 10 B.C. His original name was Marcus Iulius Agrippa. Josephus informs us that, after the murder of his father, Herod the Great sent him to Rome to the court of Tiberius, whose son Drusus became his friend. On the death of Drusus, Agrippa, who had been recklessly extravagant, was obliged to leave Rome overwhelmed with debt. After a brief seclusion, Herod the Tetrarch, his uncle, who had married Agrippa's sister Herodias, made him *Agoranomos* (Overseer of Markets) of Tiberias, and presented him with a large sum of money; but his uncle being unwilling to continue his support, Agrippa left Judaea for Antioch and soon after returned to Rome, where he was welcomed by Tiberius and became constant companion to the emperor Gaius (Caligula), then a popular favourite. Agrippa, overheard by his freedman Eutyches to express a wish for Tiberius' death and the advancement of Gaius, was betrayed to the emperor and cast into prison. In A.D. 37 Caligula, having ascended the throne, heaped wealth and favours upon Agrippa and gave him the tetrarchy of Batanaea and Trachonitis. To this he added that held by Lysanias; and Agrippa journeyed into Judaea to take possession of his new kingdom. In A.D. 39 he returned to Rome and brought about the banishment of Herod Antipas, to whose tetrarchy he succeeded On the assassination of Caligula (A.D. 41) Agrippa supported the emperor Claudius, who gave him the government of Judaea, while the kingdom of Chalcis in Lebanon was, at his request, given to his brother Herod. Thus Agrippa became one of the greatest princes of the east, the territory he possessed equalling in extent that held by Herod the Great. He returned to Judaea and governed it to the great satisfaction of the Jews. His zeal, private and public, for Judaism is celebrated by Josephus and the rabbis; and the narrative of Acts xii, telling of his persecution of the Apostles James and Peter, gives a typical example of it. Both the Acts of the Apostles and Josephus give an account of his sudden death after an exhibition of games at Caesarea. A third account says that Agrippa was assassinated by the Romans, who objected to his growing power. He had shown too independent a spirit in his attempt to strengthen the walls of Jerusalem and to summon a meeting of other client princes and after his death the emperor appointed no more kings of Judaea, but ruled the province by means of procurators

*See* articles Josephus, J A. 18 and 19 in *Ency. Bibl.* (W. J. Woodhouse), *Jewish Ency.* (M. Brann), with further references; N. S. Libowitz, *Herod and Agrippa* (2nd ed., 1898), Gratz, *Geschichte d Juden,* iii. 318–361.

**AGRIPPA, HEROD II.** (27–100), son of Agrippa, Herod I., and like him originally Marcus Julius Agrippa, was born about A D. 27, and received from Claudius the tetrarchy of Chalcis and the oversight of the Temple on the death of his uncle, Herod, A D. 48. In A.D. 53 he was deprived of that kingdom and given other provinces instead. He tried to prevent the Jews from rebelling, and when war broke out sent auxiliaries to help the Romans. He died in Rome in A D. 100. He was the seventh and last king of the family of Herod the Great. It was before him and his sister Berenice (*q v.* B.2) that St. Paul pleaded his cause at Caesarea (Acts xxvi ). He supplied Josephus with information for his history.

**AGRIPPA, MARCUS VIPSANIUS** (63–12 B C ), Roman statesman and general, son-in-law and minister of the emperor Augustus, was of humble origin. He was of the same age as Octavian (as the emperor was then called), and was studying with him at Apollonia when news of Julius Caesar's assassination (44 B C) arrived. By his advice Octavian at once set out for Rome. Agrippa played a conspicuous part in the war against Lucius, brother of Mark Antony, which ended in the capture of Perusia (40). Two years later he put down a rising of the Aquitanians in Gaul, and crossed the Rhine to punish the aggressions of the Germans On his return he refused a triumph but accepted the consulship (37) At this time Sextus Pompeius, with whom war was imminent, had command of the sea on the coasts of Italy Agrippa's first care was to provide a safe harbour for his ships, which he accomplished by cutting through the strips of land which separated the Lacus Lucrinus from the sea, thus forming an outer harbour; an inner one was also made by joining the lake Avernus to the Lucrinus (Dio Cassius xlviii. 49; Pliny, *Nat. Hist.* xxxvi. 24). About this time Agrippa married Pomponia, daughter of Cicero's friend Pomponius Atticus. Having been appointed naval commander-in-chief he put his crews through a course of training, until he felt in a position to meet the fleet of Pompeius. In 36 he was victorious at Mylae and Naulochus, and received the honour of a naval crown for his services. In 33 he was chosen aedile and signalized his tenure of office by effecting great improvements in the city of Rome, restoring and building aqueducts, enlarging and cleansing the sewers, and constructing baths and porticos, and laying out gardens He also first encouraged the public exhibition of works of art. The emperor's boast that he had found the city of brick but left it of marble ("marmoream se relinquere, quan latericiam accepisset," Suet. Aug. 29), might with greater propriety have been uttered by Agrippa. He was again called away to take command of the fleet when the war with Antony broke out. The victory at Actium (31), which gave the mastery of the world to Octavian, was mainly due to Agrippa. As a token of signal regard Octavian bestowed upon him the hand of his niece Marcella (28). We must suppose that his wife Pomponia was either dead or divorced In 27 Agrippa was consul for the third time, and in the following year the senate bestowed upon Octavian the imperial title of Augustus. Probably in commemoration of the battle of Actium, Agrippa built and dedicated the Pantheum still in existence as *La Rotonda.* The inscription on the portico states that it was erected by him during his third consulship. His friendship with Augustus seems to have been clouded by the jealousy of his brother-in-law Marcellus, which was probably fomented by the intrigues of Livia, the second wife of Augustus, who feared his influence with her husband. In 23 B.C., Agrippa went as governor to the East, ruling by means of legates, while he himself remained at Lesbos. But the death of Marcellus, which took place in the same year, obliged the emperor to look

to Agrippa as his successor He was recalled to Rome, and to strengthen the tie between him and Augustus was made to divorce Marcella and marry the emperor's daughter Julia (21), the widow of Marcellus. In 19 he was employed in putting down a rising of the Cantabrians in Spain. In 18 B.C. he received the Tribunician power for five years, and in the following year a renewal of his command in the East, where his just and prudent administration won him the goodwill of the provincials, especially the Hebrew population. His last public service was the bloodless suppression of an insurrection in Pannonia (13). He died at Campania in March of the year following his 51st year. Augustus honoured his memory by a magnificent funeral.

Agrippa was also known as a writer, especially on geography. Under his supervision Julius Caesar's design of having a complete survey of the empire made was carried out. Amongst his writings an autobiography, now lost, is referred to. Agrippa left several children; by Pomponia, a daughter Vipsania, who became the wife of the emperor Tiberius; by Julia three sons, Gaius and Lucius Caesar (adopted by Augustus as his successors) and Agrippa Postumus, and two daughters, Agrippina the elder, afterwards the wife of Germanicus, and Julia, who married Lucius Aemilius Paullus.

**AGRIPPA VON NETTESHEIM, HENRY CORNELIUS** (1486–1535), German writer, soldier, physician and by common reputation a magician. Agrippa was for many years in the service of Maximilian I., the German king, who sent him in 1510 on a diplomatic mission to England, where he was the guest of Dean Colet. From 1511 to 1518 he was in Italy in the service of William VI. of Monferrato and of Charles III. of Savoy. His interest in the occult sciences had brought him into conflict with the church at Dôle in 1509 when he lectured on John Reuchlin's *De verbo mirifico;* again at Pavia in 1515 when he lectured at the university on the *Pimander* of Hermes Trismegistus; and again at Metz in 1518, where he was town orator, for his defence of a woman accused of witchcraft. He then practised medicine in Cologne, Geneva, Freiburg and Lyons for short periods until Margaret, duchess of Savoy and regent of the Netherlands, appointed him archivist and historiographer to the emperor. Margaret's death in 1530 weakened his position, but after suffering a short imprisonment for debt at Brussels he lived at Cologne and Bonn, under the protection of Hermann of Wied, archbishop of Cologne. He then went to France, where he was arrested by order of Francis I. for some disparaging words about the queen-mother; but he was soon released, and on Feb. 18 1535, died at Grenoble. He was thrice married and had a large family. Agrippa's work, *De occulta philosophia,* which brought him into antagonism with the Inquisition, was written about 1510, partly under the influence of the author's friend, John Trithemius, abbot of Würzburg, but its publication was delayed until 1531, when it appeared at Antwerp. It is a defence of magic, by means of which men may come to a knowledge of nature and of God, and contains Agrippa's idea of the universe with its three worlds or spheres. His other principal work, *De incertitudine et vanitate scientiarum et artium atque excellentia Verbi Dei declamatio,* was written about 1527 and published at Antwerp in 1531. In it Agrippa denounces the accretions which had grown up around the simple doctrines of Christianity, and wishes for a return to the primitive belief of the early Christian church. He also wrote *De nobilitate et praecellentia feminei sexus,* dedicated to Margaret of Burgundy, *De matrimonii sacramento* and other smaller works. An edition of his works was published at Leyden in 1550 and they have been republished several times.

*See* H. Morley, *Life of H. C. Agrippa* (London, 1856); A. Prost, *Les sciences et les arts occultes au XVI. siècle: Corneille Agrippa, sa vie et ses oeuvres* (Paris, 1881); A Daguet, *Cornelius Agrippa* (Paris, 1856); J. Orsier, *H. C. Agrippa, sa Vie et son Oeuvre* (1911).

**AGRIPPINA**, the "elder," daughter of Marcus Vipsanius Agrippa (*q.v.*) by his third wife Julia, was the granddaughter of Augustus and the wife of Germanicus. She accompanied her husband to Germany, when the legions on the Rhine revolted after the death of Augustus (A.D. 14). Three years later she was in the East with Germanicus (*q.v.*), who died at Antioch in 19, poisoned, it was said, by order of Cn Calpurnius Piso, governor of Syria. Eager to avenge his death, she returned to Rome and boldly accused Piso of the murder of Germanicus. To avoid public infamy Piso committed suicide. Tiberius and his favourite Sejanus feared that her ambition might lead her to attempt to secure the throne for her children, and she was banished to the island of Pandataria off the coast of Campania, where she died on Oct 18, 33, starved to death by herself, or, according to some, by order of Tiberius. Two of her sons, Nero and Drusus, had already fallen victims to the machinations of Sejanus Agrippina had a large family by Germanicus, several of whom died young, while only two are of importance—Agrippina the "younger" and Gaius Caesar, who succeeded Tiberius under the name of Caligula. There is a portrait of Agrippina in the Capitoline Museum at Rome and a bronze medal in the British Museum, representing the bringing back of her ashes to Rome by order of Caligula.

*See* Tac. *Ann.* i.–vi ; Suetonius *Tiberius,* 53; Dio Cassius lvii. 6, lviii. 22, lix. 3; Elizabeth Hamilton, *Memoirs of the Life of Agrippina* (1804); Stahr, *Romische Kaiserfrauen* (1880).

**AGRIPPINA**, the "younger" (A.D. 16–59), daughter of Germanicus and Agrippina the elder, sister of Caligula and mother of Nero, was born at Oppidum Ubiorum on the Rhine, afterwards named in her honour Colonia Agrippinae (mod. Cologne). By her first husband, Gnaeus Domitius Ahenobarbus, she was the mother of the emperor Nero; her second husband was Passienus Crispus, whom she was accused of poisoning, in 49. After the death of Messalina, she married the emperor Claudius, her uncle, and induced him to adopt the future Nero as heir to the throne in place of his own son (Britannicus). In 54 she poisoned Claudius and secured the throne for her son. Being alarmed at the influence of the freedwoman Acte over Nero, she threatened to support the claims of the rightful heir Britannicus. Nero thereupon murdered the young prince and decided to get rid of his mother.

Pretending a reconciliation, he invited her to Baiae, where an unsuccessful attempt was made to drown her on a vessel especially constructed to founder. Eventually he had her put to death at her country house.

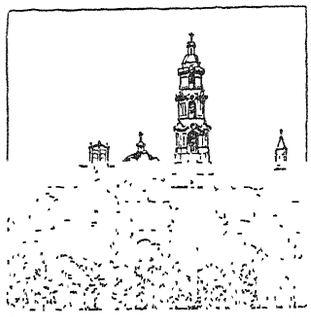
Agrippina wrote memoirs of her times, referred to by Tacitus (*Ann.* iv, 53).

*See* Tac. *Ann.* xii, xiii, xiv; Dio Cassius lix-lxi; Suetonius, *Nero,* 34; Stahr, *Agrippina, die Mutter Neros* (1880); Raffay, *Die Memoiren der Kaiserin Agrippina* (1884); B. W. Henderson, *The Life and Principate of the Emperor Nero* (1903); J. MacCabe, *Empresses of Rome,* ch. v (1911); also article NERO.

**AGRONOMY.** In the middle 1890s the term agronomy, used to designate the branch of agriculture dealing with climate, soils, fertilizers and crops (plant production), was introduced into the agricultural colleges and experiment stations of the United States. The term as now generally used indicates that branch of agriculture dealing with the science and the art of field crop culture and soil management. However, in some institutions the term agronomy is limited to the culture of field crops. (A. D. T.)

**AGUADILLA,** the largest and most important town in the northwestern section of Puerto Rico.

The population by the 1950 census of the town itself was 18,181 (1940, 13,468), while the population of the municipal district in 1950 was 43,748.



Aguadilla is situated on the west coast of Puerto Rico, on the Mona channel which connects the Atlantic ocean with the Caribbean sea. It is a seaport, but has little shipping. It is situated on the belt-line railroad which follows the coastal plains around the island and also has connection by well-built highways with the principal cities of the island.

Aguadilla has several industries and its business houses are well established. Its schools are superior, and an old church is of

especial interest.

According to tradition, Columbus' fleet of discovery in 1493 refilled its water casks at the fountain which still flows in the centre of the town. It is certain that Columbus landed in Aguadilla near the bank of the Culebrinas river. On this spot a magnificent marble cross has been erected to commemorate this historic event. There is no place under the U.S. flag on which Columbus landed except Puerto Rico. (H. M. T.; J. L.-EE.; X.)

**AGUASCALIENTES,** an inland state of Mexico, bounded north, east and west by the state of Zacatecas, and south by Jalisco. Pop. (1930) 132,900; (1940) 161,693. Area, 2,498 sq. mi. The state occupies a part of the plateau of central Mexico about 6,000 ft above sea level, extending from two spurs of the Sierra Madre, called the Sierra Fria and Sierra de Laurel, eastward to the rolling fertile plains of its eastern and southeastern districts. It is well watered by numerous small streams and one large river, the Aguascalientes or Rio Grande, and has a mild healthy climate with a light rainfall. The fertile valleys of the north and west are devoted to agriculture and the plains to stock raising Indian corn, flour, cattle, horses, mules and hides are exported to the neighbouring states. Mining industries are still undeveloped, but considerable progress has been made in manufactures, especially of textile fabrics. The state has good railway communications and a prosperous trade. The capital, Aguascalientes, named from the medicinal hot springs near it, is a flourishing commercial and manufacturing city. Pop. (1910) 45,198, (1940) 82,234. It has cotton factories, smelting works, railway shops, potteries, tanneries, distilleries and wagon and tobacco factories. It is a station on the Mexican National railway, 364 mi. N.W. of the city of Mexico, and is connected by rail with Tampico on the Gulf of Mexico. The city is well built, has many fine churches and good public buildings, street cars and electric lights. Other towns of the State are Rincón de Romos (4,460), Asientos de Ibarra (1,847) and Calvillo (3,486).

CATHEDRAL AT AGUASCALIENTES
Aguascalientes, capital of the inland Mexican state of the same name, is an industrial centre for the agricultural plateau surrounding it

**AGUE,** the common name given to a form or stage of malarial disease; the ague fit is the cold, shivering stage, and hence the word is also loosely used for any such paroxysm. (*See* MALARIA.) For "brow-ague" *see* NEURALGIA.

**AGUESSEAU, HENRI FRANÇOIS D'** (1668–1751), chancellor of France, was born at Limoges Nov. 27, 1668, the son of Henri d'Aguesseau, who held many important posts in the government. He studied law under Jean Domat and was one of the first masters of forensic eloquence in France. He was procurator general from 1700 to 1717, and defended the rights of the Gallican church against Rome in the controversy which led to the promulgation of the bull *Unigenitus.*

In 1717 he was made chancellor by the regent Orleans, but was dismissed next year because of his steady opposition to the financial projects of John Law which had been adopted by the regent. He was recalled in 1720. He then assented to the truce which Dubois made with Rome because he feared the outbreak of civil war. Popular opinion unjustly ascribed his attitude to base compliance with Dubois; but he opposed other measures of Dubois and was dismissed when the favourite became chief minister. After five years of retirement spent in study, he was recalled by Cardinal Fleury, and again became chancellor. He attempted, in vain, the codification of French law, but he executed a body of reform which placed him in the same rank with L'Hôpital and Lamoignon.

His grandson, HENRI CARDIN JEAN BAPTISTE, MARQUIS D' AGUESSEAU (1746–1826), was advocate general in the parlement of Paris and deputy in the estates-general. Under the consulate he became president of the court of appeal and later minister at Copenhagen. He was elected to the French academy in 1787.

Of H F. d'Aguesseau's works the most complete edition is that of Jean Marie Pardessus, published in 16 vol. (1818–20); his letters were edited separately by Rives (1823); a selection of his works, *Oeuvres choisies,* was issued, with a biographical notice, by E. Falconnet in 2 vol. (Paris, 1865). His works include a treatise on money; a life of his father, which is interesting from the account which it gives of his own education; and *Metaphysical Meditations.*

*See* Charles Butler, *Mem. of Life of H. F. d'* [illegible] etc (1830); Boullée, *Histoire de la vie et des ouvrages du* [illegible] *d'Aguesseau* (Paris, 1835); Fr. Monnier, *Le Chancelier d'Aguesseau* (Paris, 1860; 2nd ed., 1863).

**AGUILAR, GRACE** (1816–47), English writer, the daughter of a Jewish merchant in London, was born in June 1816 Her works consist chiefly of religious fiction, such as *The Vale of Cedars* (1850) and *Home Influence* (1847). She also wrote, in defence of her faith and its professors, *The Spirit of Judaism* (1842) and other works. She died at Frankfurt-on-Main on Sept. 16, 1847.

**AGUILAR,** or AGUILAR DE LA FRONTERA, a town of southern Spain, in the province of Córdova. Pop. of town (1940) 15,144; mun., 16,091. Aguilar "of the Frontier" was so named in the middle ages from its position on the border of the Moorish territories. Situated in the south of the fertile *Campiña de Córdoba,* its olives and white wine are celebrated; the wine is known as Amontillado, from the adjacent town of Montilla.

**ÁGUILAS,** seaport and railway terminus, southeast Spain, province of Murcia. Pop., town (1940) 11,636; mun., 15,166. Águilas is built on the landward side of a small peninsula, between two bays and has a good harbour. It is the chief outlet for the Spanish trade in esparto grass, and exports also iron ore and other mineral products of the neighbourhood.

**AGUINALDO, EMILIO** (*c.* 1869– ), Filipino insurrectionary leader, was born near Cavite, Luzon, of Chinese and Tagalog parentage. He was educated in his native town and in the University of St. Thomas, Manila. At the outbreak of the insurrection in Aug. 1896, he was mayor of Cavite Viejo. During this uprising Aguinaldo took a prominent part. But in Jan. 1898 he left the Philippines for Hong Kong, agreeing to remain permanently in exile on condition of a substantial financial reward from Spain coupled with the promise of liberal reforms. Immediately after the battle of Manila, May 1, 1898, he returned to the Philippines with the express purpose, it is said, of assisting the U.S. in the war with Spain. Obtaining the consent of the U.S. authorities, he established a native government and proclaimed a Philippine republic, of which he became the head, and reorganized the army. Because the U.S. did not recognize Philippine independence, he began hostilities against the United States on Feb. 4, 1899, by making an unsuccessful attack on Manila. During 1899 there were several severe engagements, but in the end the native troops became so hard pressed that Aguinaldo was forced to take refuge in the mountains. On March 23, 1901, he was captured by Gen. Frederick Funston at Palawan, Luzon. On April 19, 1901, Aguinaldo took the oath of allegiance to the United States and retired to private life. In 1950, Pres. Elpidio Quirino appointed him a member of the council of state.

**AGUIRRE, LOPE DE** (1508–1561), Spanish adventurer. In 1559 he joined Pedro de Ursua's expedition to the Upper Amazon, in search of El Dorado, and took part in the murder of Ursua and his lieutenant in 1561, after which Guzman was elected captain by the crew, with Aguirre as his master of the camp. The murderers declared themselves rebels, and sailed down the Amazon, plundering and putting to the sword whole villages of Indians. Aguirre established a reign of terror on board ship, which culminated in the murder of Guzman, and his own self-appointment to the position of captain. In July of 1561 the party reached Margarita Island, where they murdered the governor, robbed the royal treasury and proceeded to make incursions into the mainland of Venezuela. About this time Aguirre wrote and despatched an amazing letter to the king of Spain, accusing him of ingratitude toward himself, Aguirre, and his followers, and giving a full account of his own villainous exploits on the voyage.

Soon after, his men began to desert him and just when an attack was expected from Spanish troops, he was shot by his own fellow-rebels, in Oct. 1561.

*See* R. Southey, *[illegible] of the Crimes of Aguirre* (1821); and P. Sim[illegible] *dro de Ursua and Lope de Aguirre in search o[illegible]* (1861).

**AGUJARI, LUCREZIA** (1743–1783), an Italian operatic singer, possessed of one of the most extraordinary voices, in respect of its almost incredible compass, ever known. Mozart, who heard her at Parma in 1770, noted down some of the passages which she sang, showing her range to have extended from middle C to C in altissimo, or more than an octave above the B flat which is about the limit of the average soprano At the same time she was a brilliant executant Known (and advertised) as *La Bastardella,* on account of the circumstances of her birth, as the natural daughter of a man of rank, she paid many visits to London where she received as much as £100 a night.

**AHA,** of Shabha, an 8th-century Talmudist He was author of *Quaestiones* (*Sheiltoth*), a collection of homilies (at once learned and popular) on Jewish law and ethics This is recorded as the first work written by a Jewish scholar after the completion of the Talmud.

**AHAB,** son of Omri, king of Israel from *c* 875 to *c.* 852 B.C. (I Kings xvi 29–xxii. 40). The more important aspects of his reign, which in some respects marks the high water mark of the success of the northern kingdom, may be summarized as follows (1) *Foreign relations.*—In the reigns of Omri and Ahab the northern kingdom for the first time took an important part in international politics Omri left to his son an empire which comprised not only territory to the east of Jordan, in Gilead and probably Bashan, but also the land of Moab, whose king was tributary, while Judah (and probably Edom also) if not actually subject to Omri, was certainly a subordinate ally Ahab's marriage with Jezebel, daughter of Ethbaal of Sidon, revived an alliance which had been in abeyance since the time of Solomon But throughout the reign of Ahab a fierce border war was waged with Damascus, in which Israel, in spite of occasional victory, proved the weaker, while Mesha, king of Moab, successfully revolted and occupied the southern portions of the territory of Gad. Yet the forces of Israel retained strength enough to contribute the second largest contingent of soldiers (the largest force of chariots) to the combined armies which, under the leadership of Benhadad of Damascus, checked the westward movement of Shalmaneser III. of Assyria at Karkar in 853 B.C. After the Assyrian repulse, however, the alliance broke up, and Ahab met his death fighting the Syrians in a vain attempt to recover Ramoth Gilead. (2) *Domestic affairs.*—Contact with a wider world, and especially the alliance with Phoenicia, had far-reaching results for the kingdom of Israel itself. Jezebel attempted to introduce into religion and government elements which were common enough elsewhere in the ancient world but strange in Israel. She endeavoured to set up the worship of the Tyrian Baal in Samaria, and to maintain the familiar oriental principle of the absolute despotic power and authority of the sovereign. This roused the bitter hostility of that conservative party which clung to the sole worship of the national God, Yahweh, and at the same time held to those democratic conceptions of society which the Hebrews had brought with them from the wilderness and had consistently maintained through their history. The spirit of this party found expression in the prophet Elijah (*q.v.*), who protested alike against the establishment of the Baal priests and the judicial murder of Naboth. He and those who came after him seem to have been successful in eliminating the foreign worship, though in the end their purpose was only achieved by a bloody revolution; but they were powerless to stem the tide of social and moral deterioration. (*See* Amos.) It is to the reign of Ahab that we may trace the beginning of that sapping of the national life which led to the condemnations of the 8th century prophets and to the downfall of Samaria.

(T. H. R.)

**AHAGGAR,** general name for a large plateau region of the north centre of the Sahara, culminating about 9oom. due S. of Algiers and 1,2oom. due N. of the mouth of the Niger. The highest peaks do not greatly exceed 8,oooft. above sea-level. (*See* also Sahara)

**AHASUERUS,** a royal Persian name occurring in Ezra iv. 6, Dan. ix. 1, and throughout the book of Esther, but its occurrence in Tobit xiv. 15, in some Greek mss., is due to a copyist's blunder. It is the Latinized form of the Hebrew *Aḥašwērōš* (LXX. 'Ασσούηρος). In Ezra iv. 6 Ahasuerus is mentioned as a king of Persia, to whom the enemies of the Jews sent representations opposing the rebuilding of the temple at Jerusalem. He here occupies a place in a chronological series of those Persian rulers who were directly concerned with events of Jewish history. (*See* Ezra and Nehemiah, Books of) Immediately preceding Artaxerxes I. Longimanus, he is evidently to be identified with Xerxes. This conclusion is supported by the resemblance of the Hebrew form of the name to the Babylonian *Aḫšyarš(u)*, the Egyptian-Aramaic transliterations, etc. The old Persian form, found in inscriptions, is *Khšayāršā.*

In the book of Esther the king, at whose court the scene is laid, bears the same Hebrew name, rendered *Assuerus* in the Latin version and Ahasuerus in the English Bible (but in LXX. "Artaxerxes" throughout) Most modern scholars are agreed that here also Xerxes is the king intended (*See* Esther)

In Dan ix. 1 "Ahasuerus" (*Aḥašwērōš*) is the father of "Darius the Mede," who is said to have become king over Babylonia upon the death of Belshazzar. (*See* also v 30, vi. 1, 29.) The name seems impossible here, however, and is probably due to some accident in the literary transmission (Josephus, *Ant.* x. 11, 4, has "Astyages"). It was perhaps originally a Hebrew form of *Huwaḫšatara* (Cyaxares) No other name resembling Ahasuerus, nor any name like Darius, is to be found in the list of Median kings. We know, moreover, from the Cyrus cylinder, as well as from the Greek historians, that the immediate successor of Nabonidus and Belshazzar as ruler of Babylonia was Cyrus (he is represented in Dan. x. 1, xi. 1, as successor of this Darius). Comparison with the list of Persian kings in the book of Ezra (see above) seems to show that in the Jewish tradition Darius I. Hystaspis was placed before Cyrus as "Darius the Mede."

*See* articles "Ahasuerus" in the *Encyclopaedia Biblica,* Hastings' *Dictionary,* the *Jewish Encyclopaedia;* Driver, *Introd. to the Lit. of the Old Test.;* Torrey, *Ezra Studies,* pp. 38 *seq.,* 135 *seq.,* 141.

(C. C. T)

**AHAZ,** king of Judah. After the death of Menahem, Pekah, king of Israel, and Rezin (rather Rasun), king of Syria, allied against Assyria and invaded Judah. At the same time the Edomites recovered Elath on the Gulf of Akabah and Judah was isolated. Notwithstanding the counsel of Isaiah, Ahaz called in the aid of Tiglath-pileser I, who, after attacking the Philistines, destroyed the power of Syria, and exacted heavy tribute from Judah It was as a vassal that Ahaz presented himself to the Assyrian king at Damascus, and brought back religious innovations, on the nature of which *see* W. R. Smith, *Relig. of Semites,* pp. 485 sqq. and commentaries on II. Kings xvi. 17.

**AHAZIAH,** the name of two kings in the Bible. (1) Ahaziah, 8th king of Israel, was the son and successor of Ahab, and reigned for less than two years. On his accession the Moabites refused any longer to pay tribute. Ahaziah lost his life through a fall from the lattice of an upper room in his palace (2 Kings i. 2–17). (2) Ahaziah, 6th king of Judah, son of Jehoram and Ahab's daughter Athaliah, reigned one year. He, together with Joram, king of Israel, was slain by Jehu, son of Nimshi. He is variously called Jehoahaz and Azariah (2 Kings viii. 25–ix.28).

**AHENOBARBUS** [Lat. "brazen-bearded"], the name of a very extensive plebeian Roman family of the *gens Domitia.* The name was derived from the red beard and hair by which many of the family were distinguished. Amongst its members the following may be mentioned:—

Gnaeus Domitius Ahenobarbus, tribune of the people 104 B.C., brought forward a law (*lex Domitia de Sacerdotiis*) by which the priests of the superior colleges were to be elected by the people in the *comitia tributa* instead of by co-optation; the law was repealed by Sulla, revived by Julius Caesar and (perhaps) again repealed by Marcus Antonius, the triumvir (Cicero *De*

*Lege Agraria*, ii. 7; Suetonius, *Nero*, 2). Ahenobarbus was elected pontifex maximus in 103, consul in 96 and censor in 92 with Lucius Licinius Crassus the orator, with whom he was frequently at variance. They took joint action, however, in suppressing the recently established Latin rhetorical schools, which they regarded as injurious to public morals (Aulus Gellius xv. 11).

LUCIUS DOMITIUS AHENOBARBUS, son of the above, and husband of Porcia the sister of Cato Uticensis. Being a convinced aristocrat he opposed Pompey and Caesar while they were united, and when their friendship cooled, attached himself to Pompey. He was consul in 54 B.C., and in 49 B.C. he was appointed by the senate to succeed Caesar as governor of Gaul. After the outbreak of the civil war he commanded the Pompeian troops at Corfinium, but was obliged to surrender. Although treated with great generosity by Caesar, he stirred up Massilia (Marseille) to an unsuccessful resistance against him. After its surrender, he joined Pompey in Greece and was slain in the flight after the battle of Pharsalus (Caesar, *Bellum Civile*, i., ii., iii., Dio Cassius xxxix., xli.; Appian, B.C. ii. 82).

GNAEUS DOMITIUS AHENOBARBUS, son of the above, accompanied by his father at Corfinium and Pharsalus, and, having been pardoned by Caesar, returned to Rome in 46 B.C. After Caesar's assassination he attached himself to Brutus and Cassius, and in 43 B.C. was condemned by the *lex Pedia* as having been implicated in the plot. He obtained considerable naval successes in the Ionian sea against the triumvirate, both before and after Philippi, but in 40 B.C. became reconciled to Antony, who made him governor of Bithynia. He took part in Antony's Parthian campaigns, and was consul in 32 B.C. When war broke out between Antony and Octavian, he at first supported Antony, but, disgusted with his intrigue with Cleopatra, went over to Octavian shortly before the battle of Actium (31 B.C.). He died soon afterwards (Dio Cassius xlviii.–l.; Appian, *Bell. Civ.*, iv., v.). His son was married to Antonia, daughter of Antony, and became the grandfather of the emperor Nero.

*See* Drumann, *Geschichte Rom.*, 2nd ed. by Groebe, vol. iii. pp. 14 ff.

**AHITHOPHEL,** one of David's most trusted advisers, whose counsel was "as though one inquired of the word of God." He took a leading part in Absalom's revolt, and his defection was a severe blow to the king, who prayed that God would bring his counsel to "foolishness." At Ahithophel's advice Absalom first took the precaution of asserting his claim to the throne by seizing his father's concubines. The immediate pursuit of David was then suggested but Hushai recommended waiting till the levies of all Israel could be called up. This advice was adopted, and David had time to escape across the Jordan. Finding that his policy was neglected, and foreseeing the disaster which actually occurred, Ahithophel went home and hanged himself. (2 Sam. xv. 31–37; xvi. 20–xvii. 14, 23.)

**AHLEN,** a town in the southeast of the district of Münster, in the Prussian province of Westphalia. Pop. (1939) 25,461. It produces metalwork, enamelling, die stamping, galvanizing, etc.

**AḤMAD IBN ḤANBAL** (780–855), the founder, involuntarily and after his death, of the Ḥanbalite school of canon law, was born at Baghdad in A.H. 164 (A.D. 780) of parents from Merv, but of Arab stock. He studied the Koran and its traditions (*ḥadîth, sunna*) there and on a student journey through Mesopotamia, Arabia and Syria. After his return to Baghdad he studied under ash-Shāfi'i between A.H. 195 and 198, and became, for his life, a devoted Shāfi'ite. But his position in both theology and law was more narrowly traditional than that of ash-Shāfi'i; he rejected all reasoning, whether orthodox or heretical in its conclusions, and stood for acceptance on tradition (*naql*) only from the Fathers. In consequence, when al-Ma'mūn and, after him, al-Mu'tasim and al-Wāthiq tried to force upon the people the rationalistic Mu'tazilite doctrine that the Koran was created, ibn Ḥanbal, the most prominent and popular theologian who stood for the old view, was imprisoned and scourged. In A.H. 234, under al-Motawakkil, the Koran was finally decreed uncreated, and ibn Ḥanbal who had come through this trial better than any of the other theologians, enjoyed an immense popularity with the mass of the people as a saint, confessor and ascetic. He died at Baghdad in A.H. 241 (A.D. 855) and was buried there.

BIBLIOGRAPHY.—On his great work, the *Musnad*, a collection of some 30,000 selected traditions, *see* Goldziher in *ZDMG*, l. 465 ff. For his life and works generally, *see* W. M. **AḤMADIYYAH:** *see* ISLAM.

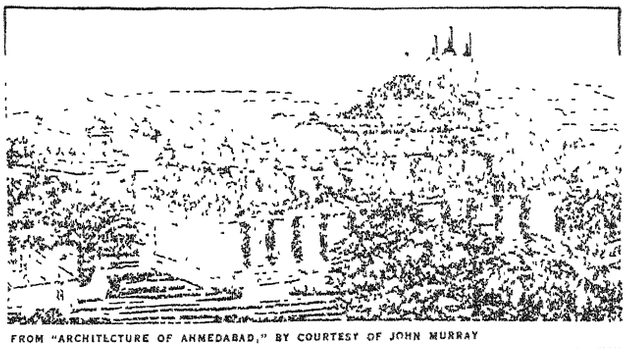
**AḤMAD SHAH** (1724–73), founder of the Durani dynasty in Afghanistan, was the son of Sammaun-Khan, hereditary chief of the Abdali tribe. While still a boy, Ahmad fell into the hands of the hostile tribe of Ghilzais, by whom he was kept prisoner at Kandahar. In March 1738 he was rescued by Nadir Shah, who soon afterwards gave him the command of a body of cavalry composed chiefly of Abdalis. On the assassination of Nadir in 1747, Ahmad, having failed in an attempt to seize the Persian treasures, retreated to Afghanistan, where he persuaded the tribes to assert their independence and accept him as their sovereign. He was crowned at Kandahar in Oct. 1747, and about the same time he changed the name of his tribe to Durani. He first crossed the Indus in 1748, when he took Lahore; and in 1751, after a feeble resistance on the part of the Mohammedan viceroy, he became master of the entire Punjab. In 1750 he took Nishapur and in 1752 subdued Kashmir. His great expedition to Delhi was undertaken in 1756 in order to avenge himself on the Great Mogul for the recapture of Lahore. Ahmad entered Delhi with his army in triumph, and for more than a month the city was given over to pillage. The shah himself added to his wives a princess of the imperial family, and bestowed another upon his son Timur Shah, whom he made governor of the Punjab and Sirhind. As his viceroy in Delhi he left a Rohilla chief in whom he had all confidence, but scarcely had he crossed the Indus when the Mohammedan wazir drove the Afghan chief from the city, killed the Great Mogul and set another prince of the family, a tool of his own, upon the throne. The Mahratta chiefs availed themselves of these circumstances to endeavour to possess themselves of the whole country, and Ahmad was compelled more than once to cross the Indus in order to protect his territory from them and the Sikhs, who were constantly attacking his garrisons. In 1758 the Mahrattas obtained possession of the Punjab, but on Jan. 6, 1761, they were totally routed by Ahmad in the great battle of Panipat. In a later expedition he inflicted a severe defeat upon the Sikhs, but had to hasten westwards immediately afterwards in order to quell an insurrection in Afghanistan. Meanwhile the Sikhs again rose, and Ahmad was forced to abandon all hope of retaining the command of the Punjab. He died in 1773, leaving to his son Timur the kingdom he had founded.

**AHMED I.** (1589–1617), sultan of Turkey, was the son of Mohammed III., whom he succeeded in 1603, being the first Ottoman sultan who reached the throne before attaining his majority. He was of kindly and humane disposition, as he showed by refusing to put to death his brother Mustafa, who eventually succeeded him. In the earlier part of his reign he gave proof of decision and vigour, which were belied by his subsequent conduct. The wars which attended his accession both in Hungary and in Persia terminated unfavourably for Turkey, and her prestige received its first check in the peace of Sitvatörök, signed in 1606, whereby the annual tribute paid by Austria was abolished. Ahmed gave himself up to pleasure during the remainder of his reign—which ended in 1617—and demoralization and corruption had become as general throughout the public service as indiscipline in the ranks of the army. The use of tobacco is said to have been introduced into Turkey during Ahmed I.'s reign.

**AHMED II.** (1643–95), sultan of Turkey, son of Sultan Ibrahim, succeeded his brother Suleiman II. in 1691. His chief merit was to confirm Mustafa Kuprili as grand vizier. But a few weeks after his accession Turkey sustained a crushing defeat at Slankamen (1691) from the Austrians under Prince Louis of Baden and was driven from Hungary; during the four years of his reign disaster followed on disaster, and on Feb. 6, 1695, Ahmed died, worn out by disease and sorrow.



**AHMED III.** (1673–1736), sultan of Turkey, son of Moham-

med IV., succeeded to the throne in 1703 on the abdication of his brother Mustafa II. He cultivated good relations with England, and he afforded a refuge in Turkey to Charles XII. of Sweden, after his defeat at Poltava (1709). Forced into war with Russia, he came nearer than any Turkish sovereign before or since to breaking the power of his northern rival, whom his grand vizier, Baltaji Mohammed Pasha succeeded in completely surrounding near the Pruth (1711) In the treaty which Russia was compelled to sign, Turkey obtained the restitution of Azov, the destruction of the forts built by Russia, and the understanding that the tsar should abstain from future interference in the affairs of the Poles or the Cossacks. Discontent at the leniency of these terms was so strong at Constantinople that it nearly brought on a renewal of the war. In 1715 the Morea was taken from the Venetians This led to hostilities with Austria, in which Turkey was unsuccessful, and Belgrade fell into the hands of Austria (1717). Through the mediation of England and Holland the peace of Passarowitz was concluded (1718), by which Turkey retained her conquests from the Venetians, but lost Hungary. A war with Persia terminated in disaster, leading to a revolt of the janissaries, who deposed Ahmed in Sept. 1730.

**AHMEDABAD**, a city and district of British India in the Northern division of Bombay. Pop. (1941) 591,267. The city was once the handsomest and most flourishing in western India, and it still ranks next to Agra and Delhi for the beauty and extent of its architectural remains. It was founded by Ahmad Shah in A.D. 1411 on a site used for earlier Hindu towns, and embellished with fine buildings of marble brought from a distance. The Portuguese Barbosa described it as "very rich and well embellished, with good streets and squares supplied with houses of stone and cement." In Sir Thomas Roe's time, A.D. 1615, "it was a goodly city as large as London." From 1411 to 1511 it grew in size and wealth; from 1512 to 1572 it declined with the decay of the dynasty of Gujarat; from 1572 to 1709 it renewed its greatness under the Moghul emperors; from 1709 to 1809 it dwindled with their decline; and from 1818 onwards it again increased under British rule.

In consequence of these changes of dynasty, Ahmedabad became the meeting place of Hindu, Mohammedan and Jain architecture. Ahmad Shah pulled down Hindu temples in order to build his mosques with the material. The Jama Masjid itself, with its 300 pillars fantastically carved, is a Hindu temple converted into a mosque.

Many of the houses are most beautifully carved and there are numerous fine mosques, tombs, etc. One of the finest is the modern Jain temple of Hathi Singh outside the Delhi gate, which was built only in 1848. Two of the windows in Sidi Said's mosque

THE TEMPLE OF HATHI SINGH AT AHMEDABAD, BUILT IN 1848 AS THE LOCAL SHRINE OF JAINISM

of filigree marble work are marvels of delicacy and grace, and finer than anything of the kind to be found in Agra or Delhi.

The modern city of Ahmedabad is situated on the left bank of the river Sabarmati; Sabarmati, on the opposite bank of the river, is practically part of Ahmedabad. It has a station on the Bombay and Baroda railway, 309 mi. from Bombay, whence branch lines diverge to Delhi, Khed Brahma and Dolka, and is the largest centre for trade and manufacture in the province after Bombay. Its native bankers, shopkeepers and workers are all strongly organized in guilds It has numerous cotton mills, about one-third of the population being dependent on the cotton industry, and factories for ginning and pressing cotton. Other industries include oil, flour and silk mills, manufactures of soap, matches, glass, tobacco and hosiery, carpet works and tanneries Ahmedabad is famous for its handicrafts, including brocades and tinsel lace, copper and brass working, jewellery and wood carving Filtered water is obtained from wells in the river bed and the main streets are lighted by electricity. The military cantonment, 3 mi. N. of the native town, is the headquarters of the northern division of the Bombay command, with an arsenal.

The district of Ahmedabad lies at the head of the gulf of Cambay, between Baroda and Kathiawar. Area 3,879 sq mi Pop (1941) 1,372,171. The river Sabarmati and its tributaries, flowing from northeast to southwest into the gulf of Cambay, are the principal streams that water the district. The northeastern portion is dotted with low hills, which gradually sink into a vast plain, subject to inundation on its western extremity With the exception of this latter portion, the soil is very fertile, and some parts are wooded The principal crops are millets, cotton, wheat and pulse The district is traversed by the Bombay and Baroda railway, and has two seaports, Dholera and Gogo, the former of which has given its name to a mark of raw cotton in the Liverpool market.

**AHMEDNAGAR**, a city and district of British India in the Central division of Bombay on the left bank of the river Sina. Pop. (1941) 54,193. The town was founded in 1494 on the site of a more ancient city, Bhingar, by Ahmad Nizam Shah, who established a new monarchy, which lasted till its overthrow by Shah Jahan in 1636. In 1759 the Peshwa obtained possession of the place by bribery, and in 1797 it was ceded to the Mahratta chief, Daulat Rao Sindhia. During the war with the Mahrattas in 1803, Ahmednagar was invested by Gen. Wellesley and captured. Restored to the Mahrattas, it again became a British possession in 1817, under the treaty of Poona. There is a large trade in cotton and silk goods, while turbans and copper and brass pots are made. There are also factories for ginning and pressing cotton, indigo works and a tannery. Ahmednagar is a station on the loop line of the Great Indian Peninsula railway, 218 mi. from Bombay, a military station of the Poona district and an important mission station.

The district of Ahmednagar is a comparatively barren tract with a small rainfall. The area is 6,646 sq.mi. The population in 1941 was 1,142,229, showing a slight increase in the decade. On the north the district is watered by the Godavari and its tributaries, the Prawara and the Mula; on the northeast by the Dor, another tributary of the Godavari; on the east by the Sephani, which flows through the valley below the Balaghat range; and in the extreme south by the Bhima and its tributary the Gor. The Sina river, another tributary of the Bhima, flows through the Nagar and Karjat talukas.

The principal crops are cotton, millet, pulse and wheat and dyes are produced

**AHMED VEFIK, PASHA** (1819–1891), Turkish statesman and man of letters, was born in Stambul and educated in Paris. He was appointed to a post in the *bureau de traduction* of the ministry for foreign affairs, and devoted his leisure to the translation of Molière's plays into Turkish and to the compilation of educational books (dictionaries, historical and geographical manuals, etc.) for use in Turkish schools. In 1847 he brought out the first edition of the *Salnameh*, the official annual of the Ottoman empire. Two years later he was appointed imperial commissioner in the Danubian principalities, and in 1851 ambassador to Persia. After his return he was appointed a member of the Grand Council of Justice, and was entrusted with the revision of the penal code and the code of procedure.

In 1860 he was sent as ambassador to Paris, to avert the intervention of France in the affairs of Syria. Ahmed Vefik held various important posts in the Turkish government during the next two decades, and was twice minister of public instruction, but the position in which he rendered his most distinguished

**Aids and the Great Charter.**—The Great Charter, as before stated, extended specially to London the limitation on baronial "aids," but left untouched its liability to tallage, a lower and more arbitrary form of taxation, which the towns shared with the crown's demesne manors, and which London resisted in vain. The two exactions, although distinct, have to be studied together, and when in 1296–97 Edward I was forced to his great surrender, he was formerly supposed by historians to have pledged himself, under *De tallagio non concedendo,* to levy no tallage or aid except by common consent of his people. It is now held, however, that he limited this concession to *aides, mises* and *prises,* retaining the right to tallage. Eventually, by a statute of 1340, it was provided that the nation should not be called upon "to make any common aid or sustain charge" except by consent of parliament. The aids spoken of at this period are of yet another character, namely, the grant of a certain proportion of all "movables" (*i.e.,* personal property), a form of taxation introduced about 1188 and of rapidly increasing importance These subsidies were conveniently classed under the vague term "aids," as were also the grants made by the clergy in convocation, the term covering both feudal and non-feudal levies from the higher clergy and proportions not only of "movables" but of ecclesiastical revenues as well.

The "knight's aid" of 1130 spoken of above is probably identical with *auxilium exercitus* mentioned in the oldest custumals of Normandy, where the phrase appears to represent what was known in England as "scutage" Even in England the phrase *"quando Rex accipit auxilium de militibus"* occurs in 1166 and appears to be loosely used for scutage.

The same loose use enabled the early barons to demand "aid" from their tenants on various grounds, such as their indebtedness to the Jews, as is well seen in the Norfolk fragments of returns to the Inquest of Sheriffs (1170).

Sheriff's aid was a local payment of a fixed nature paid in early days to the sheriff for his service. It was the subject of a hot dispute between Henry II and Becket in 1163.

(J. H. R.)

**AIGRETTE,** the long back plumes which the egret (*q.v.*) assumes in the breeding season, the use of which as ornaments in women's headdresses has become rare, owing to the protests of humanitarians because of the cruelty involved in slaughtering the birds and leaving their young to starve. The name is also given to any similar ornament, in gems, etc., to the insignia of rank of colonels in the French army and, in science, to feathery excrescences such as the *pappus* of the dandelion and the luminous rays seen diverging from the moon's edges in solar eclipses.

**AIGUESMORTES,** a town of southeast France, department of Gard, 25 mi SSW. of Nîmes on a branch line of the P.L.M. railway. Population (1936) 3,458. It occupies an isolated position in the marshy plain at the western extremity of the Rhône delta, 2½ mi. from the Gulf of Lions. Louis IX embarked from Aiguesmortes in 1248 and 1270 for the 7th and 8th crusades, and developed the town. The mediaeval fortifications which surround it are of great interest. They form a parallelogram 596 yd. long by 149 yd. broad and consist of crenellated walls from 25 to 36 ft. in height, dominated by towers, of which the Tour de Constance (N.W.), built by Louis IX, was used as a prison for Protestants after the revocation of the Edict of Nantes. The fortifications were completed under Philip III. To further the prosperity of the town a most liberal charter was granted to it, and in addition the trade of the port was artificially fostered by a decree requiring that every vessel navigating within sight of the lights should put in there. This ordinance remained in force till the reign of Louis XIV. The town, although steadily decreasing in population, remains important historically as an outstanding example of mediaeval city planning. Aiguesmortes is the meeting-place of several canals connecting with Beaucaire, Cette, the Petit Rhône and the Mediterranean. Fishing and the manufacture of soda are industries, with trade in coal, fruits and wine In the surrounding country there are important vineyards, which are preserved from disease by periodical submersion.

**AIGUILLE** (Fr. for needle), the sharp jagged point above the snow-line formed by a part of a mountain which has been split by frost action along joints or planes of cleavage with sides too steep for snow to rest upon them. Aiguilles are thus the forms left from the splitting up of the high ridges with "house-roof" structure into detached pinnacles. (*See* ARÊTE)

**AIGUILLON, EMMANUEL ARMAND DE WIGNEROD DU PLESSIS DE RICHELIEU,** DUC D' (1720–1782), French statesman, nephew of the maréchal de Richelieu, was born on July 31, 1720. He was a member of the so-called *parti dévot,* the faction opposed to Madame de Pompadour, to the Jansenists, and to the parlement. In 1753 he was appointed commandant (governor) of Brittany and was engaged in constant disputes with the Breton parlement, in 1768 returning to court, where he resumed his intrigue with the *parti dévot* and finally obtained the dismissal of the minister Choiseul (Dec. 24, 1770) When Louis XV, acting on the advice of Madame du Barry, reorganized the government with a view to suppressing the resistance of the parlements, d'Aiguillon was made minister of foreign affairs, Maupeou and the Abbé Terray (1715–1778) also obtaining places in the ministry. D'Aiguillon was blamed for having provoked the *coup d'état* of Gustavus III, king of Sweden, in 1772, although the instructions of the comte de Vergennes, the French ambassador in Sweden, had been written by the minister, the duc de la Vrillière. D'Aiguillon, however, could do nothing to rehabilitate French diplomacy; he acquiesced in the first division of Poland, renewed the Family compact, and, although a supporter of the Jesuits, sanctioned the suppression of the society. After the death of Louis XV he quarrelled with Maupeou and with the young queen, Marie Antoinette, who demanded his dismissal from the ministry (1774). He died, forgotten, in 1782.

See *Mémoires du Ministère du duc d'Aiguillon* (3rd ed., 1792), probably written by J. L. Soulavie. On d'Aiguillon's governorship of Brittany *see* Carré, *La Chalotais et le duc d'Aiguillon* (1893); Marion, *La Bretagne et le duc d'Aiguillon* (1898); and Barthélemy Pocquet, *Le Duc d'Aiguillon et La Chalotais* (1901–02). The three last have full bibliographies. *See* also Flammermont *Le Chancelier Maupeou et les parlements* (1883); [illegible] *Le Cardinal de Bernis* (1884).

**AIGUILLON, MARIE MADELEINE DE WIGNEROD DU PONT DE COURLAY,** DUCHESSE D' (1604–75), daughter of Cardinal Richelieu's sister. In 1620 she married a nephew of the Constable de Luynes, Antoine de Beauvoir du Roure, Sieur de Combalet, who died in 1622. In 1625, through her uncle's influence, she was made a lady-in-waiting (*dame d'atour*) to the queen-mother, and in 1638 was created duchess of Aiguillon. After the death of the cardinal (1642) she withdrew from the court, and devoted herself entirely to works of charity. She helped St. Vincent de Paul to establish the hospital for foundlings, and also took part in organizing the General hospital and several others in the provinces. She died on April 17, 1675. Corneille dedicated to her his tragedy of *Le Cid.*

*See* E. Fléchier, *Oraison funèbre de Mme. Marie de Wignerod, duchesse d'Aiguillon,* Bonneau-Avenant, *La duchesse d'Aiguillon* (1879); *Mémoires de Saint-Simon,* ed. by A. de Boislisle (1879 *et seq.*).

**AIGUN,** 49° 58′ N. 127° 35′ E., a treaty port on the south bank of the Amur in northern Manchuria on the extreme north-

eastern frontier of China. Population 38,112. It lies on the opposite bank to, but about 20 mi below, the Russian city of Blagoveshchensk The treaty of Aigun (1858) was one of a series of treaties which attempted to define the boundaries between the Chinese and Russian empires. With political and strategic developments along the Siberia-Manchuria frontier and with the diversion of river trade to the north Manchurian (former Chinese Eastern) railway, it has lost its former importance as an entrepôt for the shipment of cattle, meat and grains across the Amur to Blagoveshchensk.

**AIKEN,** a city of South Carolina, U.S., 17 mi. E.N.E. of Augusta, Ga., 565 ft. above sea level; the county seat of Aiken county. It is on federal highways 1 and 78 and is served by the Southern railway. Population (1950) 7,067; (1940) 6,168. The climate is unusually dry and equable. Fox hunting, pigeon shooting, polo, polo tennis, steeplechase and flat racing and golf are popular sports. With its seven polo fields, Aiken is a winter training ground for this game. Aiken was settled early in the 19th century and was incorporated in 1835. It was on the line of one of the earliest railways, and was named after the first president of that road, William Aiken (1806–87), who was governor of the State (1844–47).

**AIKIN, JOHN** (1747–1822), English physician and author, was born at Kibworth-Harcourt on Jan. 15, 1747, and died at Stoke Newington, London, on Dec. 7, 1822. He practised as a consulting physician in London from 1792 onwards, but gradually became absorbed in literary pursuits. Aikin and his sister, Anna Letitia Barbauld, wrote popular books which had a great vogue. Their admirable miscellany, *Evenings at Home* (1792–95) was translated into many European languages. Aikin's voluminous works include *General Biography* (1799–1815), and *Lives of John Selden and Archbishop Usher* (1812).

His daughter, LUCY AIKIN (1781–1864), born at Warrington on Nov. 6, 1781, wrote several books for children, including versions of classical stories written in metre. She also wrote: a novel, *Lorimer* (1814); *Memoirs of the Court of Queen Elizabeth* (1818); *Memoirs of the Court of James I.* (1822); *Memoirs of the Court of Charles I.* (1833) and a *Life of Addison* (1843). Miss Aikin died at Hampstead on Jan. 29, 1864.

*See* a *Memoir of John Aikin, with selections of his miscellaneous pieces* (1823), by his daughter; and the *Memoirs, Miscellanies and Letters of Lucy Aikin* (1864), including her correspondence (1826–42) with William Ellery Channing, edited by P. H. Le Breton.

**AILANTHUS** (more correctly *ailantus,* from *ailanto,* an Amboyna word probably meaning "Tree of the Gods," or "Tree of Heaven"), a genus of trees belonging to the quassia family (Simarubaceae). The best known species, tree of heaven or Chinese sumac (*Ailanthus altissima*), is a handsome, rapidly growing tree with spreading branches and large pinnately compound leaves bearing many lance-shaped leaflets with conspicuous glandular bases. The small greenish flowers are borne in branched panicles; the staminate (male), upon opening, exhale a most disagreeable odour. The fruit is a samara with a single centrally disposed seed in the elliptical, twisted, fibrous wing. This tree, which is a native of China and Japan, was introduced into England in 1751 and is a favourite in parks and gardens. It has been planted extensively in the eastern United States and is one of a few trees capable of thriving in smoky atmospheres adjoining industrial centres. Two other species, *A. imberbiflora* and *A. punctata,* are Australian trees of secondary importance; *A. excelsa* is a common tree in India. (E. S. HR.)

**AILANTHUS, CYNTHIA** or **ERIA SILK MOTH** (*Philosamia cynthia*), a member of the so-called "wild" silk moths, ranging in many races and strains from China to Timor. It is olive or brown with a translucent white crescent on each wing. The caterpillar (the eria silkworm) is green with blue knobs; and the chief commercial strain (*P. c. ricini*) feeds on the castor oil plant. One of the races feeding on Ailanthus (*P. c. advena*) was introduced from China to France and thence to the U.S., and is established in France, Germany and along the Atlantic coast. Other races feed on Ilex, Zanthoxylum and other trees. (*See* SILK AND SERICULTURE: *Wild Silks.*)

*See* H. Rebel, "Revision des Formenkreises von *Philosamia cynthia* Dru.," *Annalen des naturhistorischen Museums in Wien,* xxxix 154–176, 1925 (races); Schüssler, "Saturniidae," *Lepidopterorum Catalogus,* lv, 24–41, lxv, 517–564, 733, bibliog. (1934). (W. T. M. F.)

**AILERON,** a hinged or movable portion of an aeroplane wing, the function of which is to impress a motion on the aeroplane about its longitudinal axis. Situated generally at the rear edge of the wing and at or near the wing tip, the ailerons are connected to the control column by wires or push-pull rods in such a way that a movement of it, e.g., to the right, raises the aileron on the right wing and lowers that on the left wing, causing the aeroplane to bank for a turn to the right.

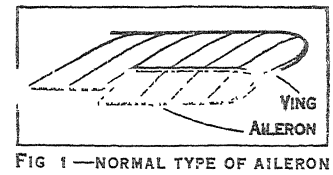

FIG. 1.—NORMAL TYPE OF AILERON
The banking of an aeroplane in turning is brought about by two ailerons, one on the rear edge of each wing. One goes up as the other goes down

Ailerons of the type shown in fig. 1 are effective in normal flight but when the aeroplane is stalled (as in the last few seconds before a normal landing) they become less effective. Great attention has therefore been devoted to aileron design in aerodynamic research laboratories throughout the world. The mounting of automatic slots of the Handley-Page type (*see* AEROPLANE) along the leading edge of the wing is one of several effective methods which have been developed to retain aileron action beyond the usual stalling point. (D. SE.)

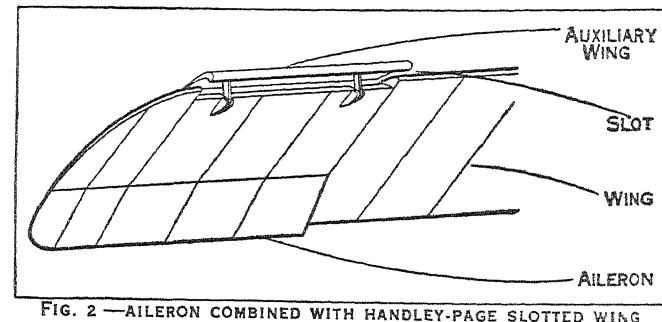

FIG. 2.—AILERON COMBINED WITH HANDLEY-PAGE SLOTTED WING
The purpose of this auxiliary wing is to remove one of the most serious risks of flying. In stalling the ailerons become ineffective. By this device the "slot" opens automatically when the wing stalls and this renders the aileron effective. The illustration shows a right wing seen from below

**AILLY, PIERRE D'** or PETRUS D'ALLIACO (1350–1420), French churchman and schoolman, was born at Compiègne and studied at the College of Navarre of the University of Paris. He became master of the college in 1384 and later obtained the highest dignity in the university, the chancellorship of Notre Dame. John Gerson was one of Ailly's pupils and his lifelong friend. The two men played an important part in the later history of the papal schism. Pierre d'Ailly acted as spokesman of the university before the king's council (May 20, 1381) with the proposal that the best way of ending the scandal of the existence of two popes, Urban VI. at Rome and Clement VII. at Avignon, was the summoning of a general council. The suggestion was unacceptable and Ailly retired from Paris for some time. As master of the College of Navarre he was twice sent by the university on missions to Clement VII., and on the death of that pope, he was sent by the king to congratulate Clement's successor, Benedict XIII. His acceptance of that mission displeased the university, which was already beginning to demand the resignation of both popes as a preliminary to the re-unification of the church. Suspicion of his attitude was deepened by his nomination by Benedict XIII. as bishop of Le Puy (1395) and then bishop of Cambrai (1397). At the ecclesiastical council, held in Paris in 1406, Ailly, by the king's order, defended Benedict XIII., and it was not until the convocation of the general Council of Pisa (1409) that he forsook Benedict's cause and returned to the point of view of the University of Paris, of which he had been the champion before his preferment. He and Gerson urged that the unity of the church could only be restored by a general council which, in case of schism, would be supreme and legitimate even though it were not convoked by the pope. The nominee of the Council of Pisa died within a year. His successor, John

XXIII, gave Ailly the bishopric of Orange and made him a cardinal. Nevertheless Ailly was one of the most formidable adversaries of John XXIII. at the Council of Constance (Nov. 1414–April 1418). He maintained that, as the decisions of the Council of Pisa had not been accepted and there were now three "popes," it was necessary to begin *de novo* and treat the claims of all three alike, and he made serious depositions against John. The theory put forward by Ailly and Gerson that the general council had jurisdiction over the pope himself was a dangerous one, and, according to later decisions, even heretical; but both men were seeking an outlet from an impossible situation Ailly found in the end an ingenious compromise on the rights of the Sacred College and the council and the schism was healed by the appointment of Martin V.

During the Council of Constance, Ailly had earned the hatred of the Anglo-Burgundians by trying to reduce the power of the English by contesting their right to form one of the four separate nations. He was compelled to retire to Avignon, where he died on Aug. 9 1420.

Pierre d'Ailly's written works are numerous. Many of them were published with the works of Gerson (by Ellies du Pin, Antwerp, 1706); others appeared in the 15th century, probably at Brussels; and there are many treatises and sermons still unpublished. In philosophy he was a nominalist.

BIBLIOGRAPHY.—P. Tschackert, *Peter von Ailli* (Gotha, 1877); L. Salembier, *Petrus de Alliaco* (Lille, 1886); H. Denifle et Em. Chatelain, *Chartularium Universitatis Parisiensis*, t. iii. (1894); N. Valois, *La France et le grand schisme d'Occident* (1896–1902); and *Bibliothèque de l'école des chartes*, vol. lxv., p. 557–574 (1904).

**AILSA CRAIG,** an island rock at the mouth of the Firth of Clyde, 10m. W. of Girvan, Ayrshire, Scotland. It is of conoidal form, with an irregular elliptic base, and rises abruptly to a height of 1,097ft. The only side from which the rock can be ascended is the east, the other sides being for the most part perpendicular, and generally presenting lofty columnar forms, though not so regular as those of Staffa. The island is composed of micro-granite with riebeckite, of great interest on account of the rare occurrence of this type in Britain. It is fine-grained and of a greyish colour, and may be of Tertiary age Pebbles of this rock were carried far south (*e.g.* to Welsh shores) by glaciers of the Ice age. The rock is a favourite material for curling-stones. Hence curling-stones are popularly known as "Ailsas" or "Ailsa Craigs." The rock is also used for paving stones. A columnar cave exists towards the north side of the island, and on the east are remains of a tower. Two springs occur and some scanty grass affords subsistence to rabbits, and, on the higher levels, to goats. The precipices have large breeding colonies of gannets and other sea birds which spend the winter months at sea. A lighthouse on the south side flashes a light visible for 13 miles. Pop. (1931) 11.

**AIMAK,** the name of nomadic or semi-nomadic Mongolian tribes inhabiting the north and north-west Afghan highlands north of Herat. *Aimak* is a Mongolian word meaning "clan" or "section of a tribe." They were originally known as "chahar (the four) eimaks," because there were four principal tribes: the Taimani, the Ferozkhoi, the Jamshidi and the Hazara. They number about 250,000, and speak a dialect akin to Kalmuck. They are Sunnite Mohammedans.

**AIMARD, GUSTAVE,** the pen-name of OLIVIER GLOUX (1818–83), French novelist, who was born in Paris Sept. 13, 1818, and died there June 20, 1883. He made use of the materials collected in a roving and adventurous youth and early manhood in numerous romances in the style of J. Fenimore Cooper. Among the best of them are: *Les Trappeurs de l'Arkansas* (1858); *La grande flibuste* (1860); *Nuits mexicaines* (1863); *La Forêt vierge* (1870)

**AIMOIN** (*c.* 960–*c.*1010), French chronicler, spent the greater part of his life in the monastery of Fleury. His chief works are. *Historia Francorum* or *Libri V de gestis Francorum*, a history of the Franks from the earliest times to 633, which was continued by other writers and brought down to the middle of the 12th century; a life of Abbo, abbot of Fleury; and books ii. and iii. of the *Miracula S. Benedicti.*

BIBLIOGRAPHY.—The *Historia* is printed in *Monumenta Germaniae historica: Scriptores*, Band xxvi.; and the *Vita* and the *Miracula* in Mabillon, *Acta sanctorum ordinis S. Benedicti* (Paris, 1668–1701). Some fragments by another Aimoin, a monk of St. Germain-des-Prés, are printed in *Historiae Francorum Scriptores*, tome ii. (1639–49). See *Histoire littéraire de la France*, tome vii. (1865–69).

**AIN,** a department of eastern France, formed from Bresse, the Pays de Dombes on the lowland and the Pays de Gex, Valromey and Bugey among the high parallel scarps of the Jura reaching south to the Rhône between Geneva and Lyons. Area 2,249 sq.mi. Pop. (1936) 316,710. The name is that of the river which roughly separates the two first from the other districts, running north to south at first between outer hill ranks and then along the foot of the highland to join the Rhône. The western boundary is the Saône, the southern the Rhône, the eastern Switzerland and the northern the departments of Saône-et-Loire and Jura, the boundary over against the latter being closely linked with that of old between Burgundy and Franche Comté. The Pays de Gex includes some of the highest Jura scarps (Crêt de la Neige 5 653-ft.), the Pays de Valromey flanks on the west the deep Rhône gorge below Bellegarde, the Pays de Bugey is the south-pointing triangle of the Rhône focussing on Belley. West of the hills, Bresse occupies the fertile north part of the department and is effectively drained to the Saône, thus contrasting with the Pays de Dombes, mantled in boulder clay and possessing endless pools and marshes with, still, a good deal of consequent malarial trouble. The summers are warm in the lowland but the winters, generally, are sharp, the rainfall rises well above 1 metre per annum in the highland. The farms of Bresse are famous for pigs and poultry and the latter (especially geese) are also bred, in Dombes, which also raises horses In the Jura hill country, pastures feed sheep and cattle from which cheese is produced, while many slopes are well forested. Bresse produces considerable cereal and other crops but the rest of the department is thus concerned mainly with stock-raising or with activities connected with its forests (of fir and oak) or with extensions of the silk industry from Lyons just beyond the south-west corner of the department, thanks to the water power available from the rivers among the gorges of the limestone country. Bourg is the capital of the department; the four arrondissements of which take their names from Bourg, Belley (the seat of a bishop in the archiepiscopal province of Besançon) and Nantua. The departmental appeals are heard at the court of Lyons and the department is also under Lyons educationally. Bourg (*q.v.*) is a market town specially known in connection with the famous church of Brou, wrongly described in Arnold's well known poem as being in Savoy. Among silk towns one may mention Jujurieux, Tenay, St. Rambert, St. Bernard en Bugey; Bellegarde and St. Rambert make wood pulp; and Oyonnax, a rather larger town than several of the others, north of Nantua, makes articles in wood and horn and is specially well known for its combs. Seyssel, on the far east, yields asphalt and many parts of the department give building stones, cement or potter's clay. There is a good tourist industry for winter sports, angling, etc., and some of the gorges and ridges are very striking; near Bellegarde, at the Perte du Rhône, that great river formerly disappeared down a fissure. Though the main P.L.M. railway from Dijon to Lyons lies west of the Saône, and so outside the department, the main line from Paris to Geneva runs through Bourg and Ambérieu to Bellegarde; both the Saône and the Rhône are navigable for considerable lengths along the confines of the department.

**AINGER, ALFRED** (1837–1904), English divine and man of letters, was born in London on Feb. 9, 1837, the son of an architect. He was educated at King's College, London, and at Trinity College, Cambridge, and was ordained in 1860 to a curacy at Alrewas, near Rugeley. His connection with the Temple Church, in London, began in 1866, when he was appointed reader; and in 1894 he succeeded Dr. Vaughan as master. In 1887 he was presented to a canonry in Bristol cathedral, and he was chaplain-in-ordinary to Queen Victoria and King Edward VII. He died on Feb. 8, 1904. Canon Ainger's gentle wit and humour, his generosity and lovable disposition, endeared him to a wide circle. In literature his name is chiefly associated with his sympathetic appreciation of Charles Lamb and Thomas Hood.

His works include: *Charles Lamb* (1882) and *Crabbe* (1903) in the "English Men of Letters" series, editions of Lamb's *Essays of Elia* (1883) and of his *Letters* (1888; 2nd ed., 1904), of the *Poems* (1897) of Thomas Hood, with a biographical introduction; *The Life and Works of Charles Lamb* (1899–1900); articles on Tennyson and Du Maurier in the *Dictionary of National Biography; The Gospel and Human Life* (1904), sermons; *Lectures and Essays* (1905), edited by the Rev. H. C. Beeching

*See* Edith Sichel, *The Life and Letters of Canon Ainger* (1906).

**AINHARDUS:** *see* EINHARD.

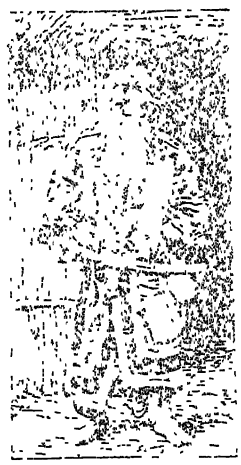
**AINMÜLLER, MAXIMILIAN EMMANUEL** (1807–1870), German artist and glass-painter, was born at Munich on Feb. 14, 1807. In 1828 he was appointed director of the newly-founded royal painted-glass manufactory at Munich. The method which he gradually perfected there was a development of the enamel process adopted in the Renaissance, and consisted in actually painting the design upon the glass, which was subjected, as each colour was laid on, to carefully-adjusted heating. The earliest specimens of Ainmüller's work are to be found in the cathedral of Ratisbon. With a few exceptions, all the windows in Glasgow cathedral are from his hand. Specimens may also be seen in St. Paul's cathedral, and Peterhouse, Cambridge, and Cologne cathedral contains some of his finest productions. Ainmüller had considerable skill as an oil-painter, especially in interiors. He died on Dec. 9, 1870.

**AINSWORTH, HENRY** (1571–*c.* 1622), English Nonconformist divine and rabbinical scholar, was born at Swanton Morley, Norfolk. He was a scholar of Caius College, Cambridge, joined the Puritan party in the church, and eventually the Separatist. Driven abroad in the persecution of 1593, he found a home in "a blind lane at Amsterdam." He acted as "porter" to a scholarly bookseller in that city, who, on discovering his skill in Hebrew, enabled him to continue his Hebrew studies. When part of the London church, of which Francis Johnson (then in prison) was pastor, reassembled in Amsterdam, Ainsworth was chosen as their doctor or teacher.

In 1596 he drew up a confession of their faith, which he reissued in Latin in 1598. Johnson joined his flock in 1597, and in 1604 he and Ainsworth composed *An Apology or Defence of such true Christians as are commonly but unjustly called Brownists.* In 1610 he was forced reluctantly to withdraw, with a large part of their church, from Johnson and his adherents on a question of church government, Ainsworth taking the more congregational view. (*See* CONGREGATIONALISM.) But in spirit he remained a man of peace. The fruit of his rabbinical learning appeared in his *Annotations*—on *Genesis* (1616); *Exodus* (1617); *Leviticus* (1618); *Numbers* (1619); *Deuteronomy* (1619); *Psalms* (including a metrical version, 1612); *Song of Solomon* (1623). These were collected in folio in 1627, and again in 1639. From the outset the *Annotations* took a commanding place, especially among Continental scholars.

BIBLIOGRAPHY.—J. Worthington's *Diary* (Chetham Society), by Crossley, i. 263–266; works of John Robinson (1851); H. M. Dexter, *Congregationalism of the Last Three Hundred Years* (1880); W. E. A. Axon, *A Forgotten Puritan, the Puritan Commentator* (1889); F. J. Powicke, *Henry Barrow and the Exiled Church of Amsterdam* (1900); J. H. Shakespeare, *Baptist and Congregational Pioneers* (1906).

**AINSWORTH, ROBERT** (1660–1743), English schoolmaster and author, was born at Eccles, near Manchester, in Sept. 1660. Ainsworth's name is associated with his Latin-English dictionary, begun in 1714 and published in 1736 as *Thesaurus linguae Latinae compendiarius.* He died in London, April 4, 1743.



**AINSWORTH, WILLIAM HARRISON** (1805–1882), English novelist, was born at Manchester, Feb. 4, 1805. He was educated for the law, but at the age of 21 he married a daughter of John Ebers, the publisher, and followed his father-in-law's profession for a short time. A novel called *Sir John Chiverton,* in which he had a share, won the praise of Sir Walter Scott, and he turned to novel-writing. *Rookwood* (1834), with its description of the ride of Dick Turpin to York, had an immediate success. He published about 40 "historical" novels, of which the best known are *Jack Sheppard* (1839), *The Tower of London* (1840), *Old St Paul's* (1841) and *Windsor Castle* (1843). He edited *Bentley's Miscellany,* in which *Jack Sheppard* was published as a serial, and in 1842 he became proprietor of *Ainsworth's Magazine.* In 1853 it ceased to appear, and Ainsworth bought the *New Monthly Magazine.* He died at Reigate, Jan. 3, 1882.

*See* S. M. Ellis, *William Harrison Ainsworth and his Friends* (London, New York, 1911).

**AINTAB** or GAZIANTEB (anc. DOLICHE), a city of Anatolia, Turkey, just outside Syria, pop. (1940) 57,132 (two-thirds are Muslim, mainly of Turkoman origin and there are 15,000 Armenians). In ancient times (2nd Mil. B.C.) Aintab was in the Hittite area and is probably of Hittite origin. Duluk, the site of *Doliche,* famous for the worship of Zeus Dolichenus (Baal), is marked by a mound two hours distant to the northwest. In Crusading times its strong castle (*Hamtab*) was a strategic point of importance and was captured by Saladin in 1183. It served as the last base of Ibrahim Pasha before his victory over the Turks at Nezib, 25 mi. to the northeast (1839). In the winter of 1920–21 the armed opposition of the Turkish nationalists to the French occupation of north Syria centred in Aintab, which became the "Verdun of Anatolia." After an investment lasting six months, despite determined Turkish efforts to relieve it, the city surrendered to the French troops. France returned it to Turkey under the Angora treaty of Oct. 30, 1921.

The modern city stands high (3,500 ft.) in the open, treeless valley of the Sajur, a tributary of the Euphrates, some 65 mi. N.E. of Aleppo. Important educational and medical work is carried on by the American Mission Board in their college (founded 1874) and girls' seminary. There is also a Franciscan mission. Manufactures include striped dress materials (the chief of which is a mixture of silk and cotton), black goats' hair cloth for tents, morocco leather (*sakhtiyan*) made from goats' skins (it is estimated that nearly 400,000 are tanned here annually), "Aleppo soap" made from olive oil, *Pekmez,* a sweet paste made from grapes, and the dyeing of yarns. The exports include pistachio nuts, tobacco, cotton and cereals.

**AINU,** who are racially closely akin to, if not identical with, the Neolithic inhabitants of Japan (*see* JAPAN: *History*) are now very reduced in numbers and live in Hokkaido, the northern island of Japan, in part of Saghalien, and have kinsfolk in the Ryukyu archipelago (*q.v.*). They are dwindling fast and are unable to compete with the advance of Japanese civilization. Physically they are probably the remains of an old Proto-Nordic population once widely spread over Northern Asia, and are certainly the relics of a very old human stock. Their culture recalls in many ways stone age man and they have preserved the very earliest stage of agriculture, when the men are still hunters but the women have developed beyond the mere collecting stage and are beginning actually to plant crops.

AN AINU VILLAGE CHIEF
The Ainu are now under Japanese rule, but in former times their affairs were administered by hereditary chiefs, three in each village

The Ainu religion is closely akin to the animistic religion practised by various primitive peoples of northern Asia, and they are particularly liable to that peculiar kind of religious ecstasy known as Arctic hysteria. One of their special cults is that of the bear. This animal is caught as a cub, and is carefully tended by the women who will even suckle it. At about three years old the bear is sacrificed with elaborate ceremony. In most of the Ainu villages, the special wooden cages in which the bears are kept can be seen. Prominent also in the villages are sticks which have been whittled (*inao*) and the shavings left on. The sticks are stuck in the ground and have a religious significance.

**AÏR,** a region lying between 15° and 19° N. and 6° and 10° E., and included in the province of Agades in Niger colony, French West Africa. It is one of several upland regions of the Sahara. It consists basically of broadly rounded, ancient granitic hills rising to an average elevation of 2,500 ft. These are overlaid by scattered lava flows and are crossed from east to west by wide, shallow valleys which are usually dry. Several volcanic ranges, reaching to 5,000-ft. elevation, rise with startling abruptness above the general level of the land. Because of elevation, Air is considerably more moist than most of the Sahara Rainfall at Agades in the lower, southern part of the region averages seven inches per year and is concentrated from May through September. Higher elevations receive more rain, but seasonal distribution is the same. Though there are no permanent rivers in Air, the valleys become broad, rapidly flowing streams several times during each rainy season. Most of the water runs off westward to the broad, lower plain of Talak where the soil moisture thus derived provides plentiful grass cover. A small amount drains eastward to disappear beneath the desert sands of Ténéré.

In contrast to the barren hill and mountain slopes, many of the valleys of Air are densely covered with brush and tree vegetation or grasses through which are scattered a few small trees.

In 1944, Aïr's population totalled about 20,000; that of Agades was about 3,200. The inhabitants are Tuareg, or Berbers, with a strong admixture of Negroid blood. These people are dominantly nomadic; yet they maintain permanent settlements which serve as market centres and caravan relay stations. Agriculture is unimportant, but camels, sheep and a few cattle are pastured.

Agades is the capital and is on the trans-Saharan bus route from Algiers to Zinder. Caravan routes, of which that eastward to the Bilma salt oasis is the most important, pass through the town Its population was greatest, more than 30,000, in 1591, but decline of caravan trade and treatment accorded the Tuareg by the French after the revolt of 1917 caused its modern decline.

**AIR,** the atmosphere that surrounds the earth. With the development of analytical and especially of pneumatic chemistry, the air was recognized not to be one homogeneous substance, as was long supposed, and different "airs," or gases, came to be distinguished. At the end of the 18th century oxygen gas was known as *dephlogisticated air,* nitrogen or azote as *phlogisticated air,* hydrogen as *inflammable air,* carbonic acid gas as *fixed air.* The name is now ordinarily restricted to atmospheric air (*see* ATMOSPHERE)

The sense of atmosphere or environment may have led to the further use of the word "air" to mean "manner" or "appearance"; and so to its employment (*cf.* Lat. *modus*) in music for "melody." (*See* ARIA.)

**AIRAY, HENRY** (1560?–1616), English Puritan theologian, was born at Kentmere, Westmorland, but no record remains of the date of either birth or baptism.

According to Anthony Wood's *Athenae,* Airay "was sent to St. Edmund's hall in 1579, aged nineteen or thereabouts. Soon after he was translated to Queen's College, where he became *pauper puer serviens;* that is, a poor serving child that waits on the fellows in the common hall at meals, and in their chambers, and does other servile work about the college." He was graduated from Queen's College as B A. on June 19, 1583; and, after receiving M.A. and B.D. degrees, he became D.D. at his college on June 17, 1600. "About the time he was master" (1586) "he entered holy orders, and became a frequent and zealous preacher in the university."

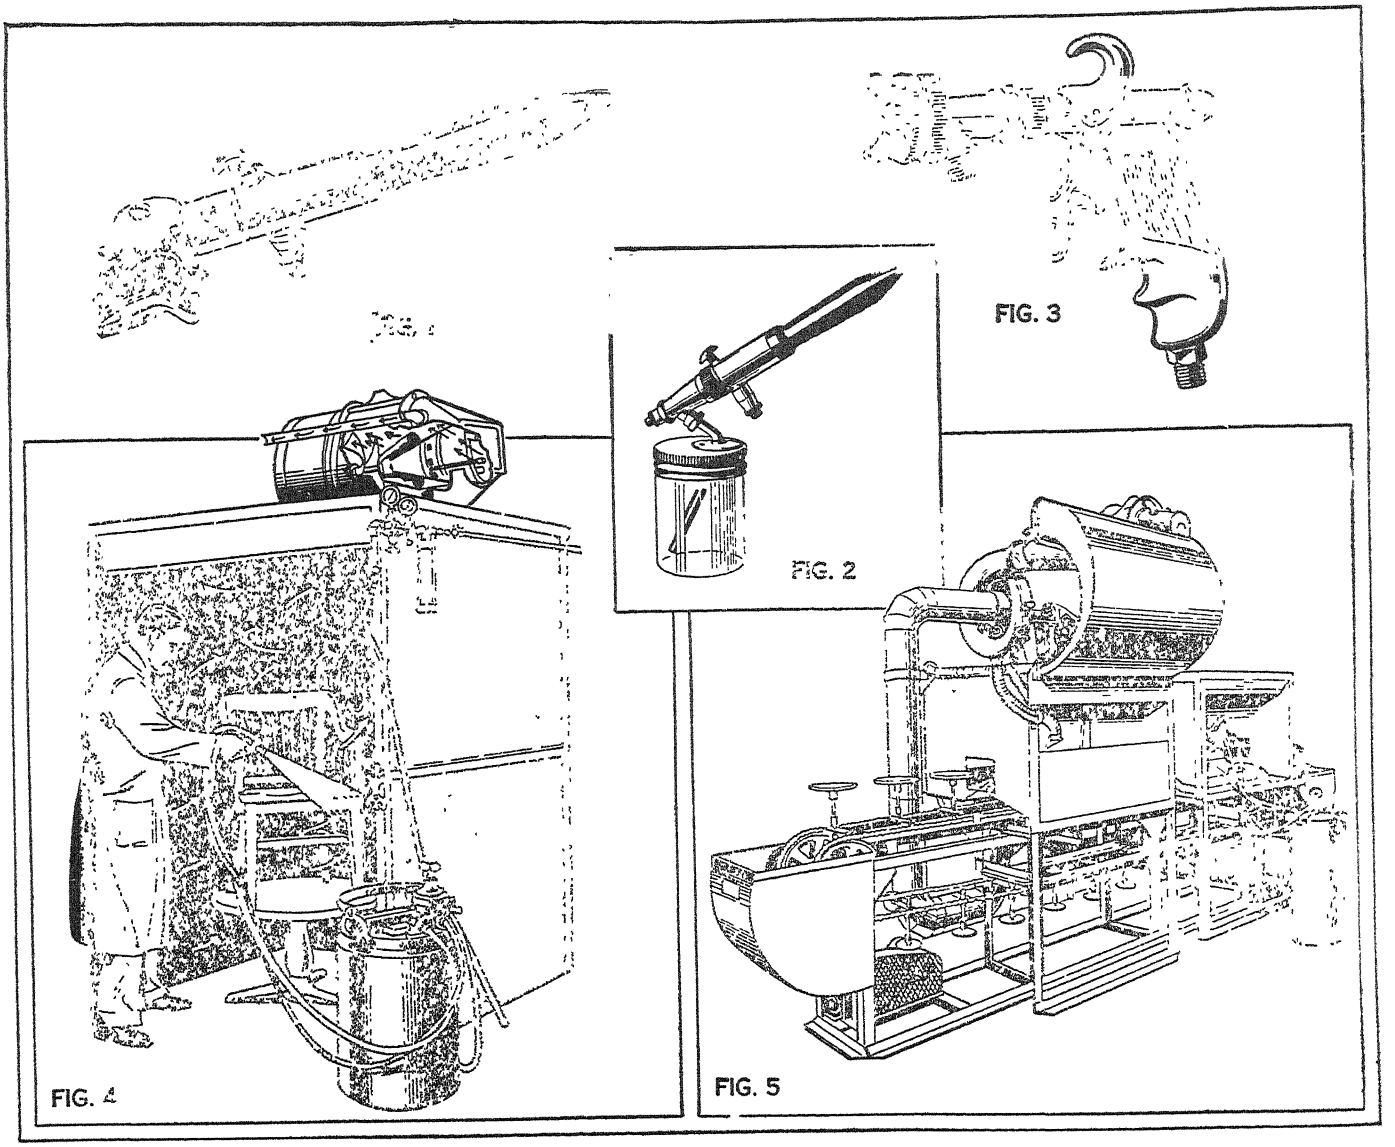
His *Commentary on the Epistle to the Philippians* (1618, reprinted 1864) is a specimen of his preaching before the college and his enunciation of Calvinism. In 1598 he was chosen college provost, and in 1606 he was vice-chancellor of the university. He was also rector of Otmore (or Otmoor) near Oxford.

He died on Oct. 6, 1616. His character as a man, preacher, theologian, and as an important ruler in the university, will be found portrayed in the Epistle by John Potter, prefixed to his *Commentary.* He must have been a fine specimen of the more cultured Puritans—possessed of a robust common sense in admirable contrast with some of his contemporaries.

**AIR BLADDER,** the name given to a structure present in all bony fishes (teleosts) and somewhat homologous with the lungs of land vertebrates The functions of this organ, which contains gas having a high percentage of oxygen, are obscure. hydrostatic uses are attributed to it, but its function doubtless varies. In some fishes (especially Siluroidea), it is connected with the internal ear by a chain of bones, the Weberian ossicles, and in these forms it is possibly concerned with hearing. It usually retains a connection with the alimentary canal (except in most Acanthopterygii, *q.v.*), but is normally dorsal to it (*See* FISHES.)

**AIRBRUSH,** a machine used for applying liquid colouring powders, flock, latex and glazes to a surface by means of compressed air The use of compressed air for the atomization of liquids has been known for many years, but it is only in the last 35 years that the principle has been successfully applied to the application of all types of coating materials in commercial and industrial enterprises, and today there is hardly an institution anywhere whose product requires finishing that does not employ this method of application. The early successful use of airbrushes was in the field of art for retouching, etc.

The airbrush shown in fig 1 (p. 447) is used in drawing the most delicate hairline work, as well as photographic retouching It is a common implement in all large newspaper art departments Fig. 2 illustrates the next step toward a commercial airbrush, this style being used for decorative and show-card work



The natural evolution of the airbrush that was used by the artist brought about the present industrial type (fig. 3) which is used in practically every automobile and furniture factory, or any industry applying liquid finishes to their product This is a universal airbrush, inasmuch as it may be used with any style of fluid supply, gravity (overhead bucket), pressure tank and cup (either syphon or gravity), thus making the airbrush applicable to all purposes. The heads for this type are made in 12 sizes, all interchangeable, thus adapting the airbrush to all consistencies of material. The production of as many as 5,000 automobiles per day could never have been reached were it not for the airbrush, which makes it possible to coat a body in less than one minute. Fig. 4 shows an industrial installation as used for the finishing of furniture, the booth and ventilating equipment being very necessary to carry off the fumes and excess spray.

Fig. 5 illustrates an automatic adhesive and flocking unit such as used by largest industrial organizations for high-speed daily production. In this unit, the airbrushes are operated automatically. In the section to the right the automatic airbrush applies the adhesive or binder and in the second station at the left the specially designed airbrush applies the flock, the unit reclaiming all unused material. Daily production in eight hours is 11,000 disks. Contract painters and large railroad companies also use the airbrush for general painting on buildings and bridges, effecting large savings, in addition to the fact that they are able to do the work in season.

Portable air-painting units for both electric and gasoline (petrol) engine operation are universally selected for outside air-painting jobs. Airbrushes are now made to function in every capacity from that of a cement mixture to the most delicate art work.

**AIR CONDITIONING.** The term is derived from the word conditioning which was applied to the determination of the moisture content of textiles, and covers the treating of air in an enclosure to regulate its moisture content, temperature, purity and usually its circulation. For increasing human comfort and for the manufacturing or processing of certain materials, an accurate control of the moisture content of the air is most important. It is sometimes roughly effected by adding water vapour or mist directly to the enclosed air, but more precisely by using an air-conditioning apparatus by which the air is purified and its temperature and moisture definitely controlled before it is introduced into the space to be conditioned.

Originally only places where equable and moist climatic conditions prevail, such as Lancashire, Eng., and the Fall River district in Massachusetts, could be chosen for the building of cotton mills. Then moisture was added to the air by evaporating water in steam pots. This method sufficed for small mills but was inadequate in the larger mills because of the heat generated by the

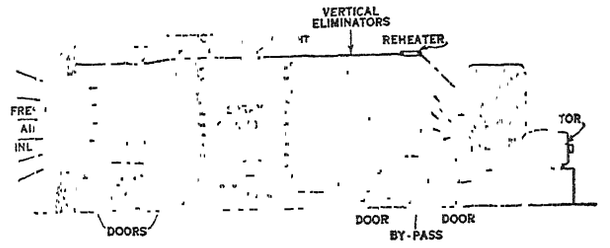
great concentration of machinery. In the latter half of the 19th century the direct introduction into the room of an atomized spray of water both cooled and moistened the air, thus making it practicable to spin fine cotton yarns in all climates. At about the same time moist air was supplied to malting floors by passing the air through coke filters over which water trickled, or through a large series of wetted baffle plates. In 1897 Joseph McCreary of Toledo, O., patented an air washer intended primarily for purifying the air, but incidentally it cooled it and increased the moisture content. In 1906 Stuart W. Cramer of Charlotte, N.C., and Willis H. Carrier of Buffalo, N.Y., working independently, made two important contributions to the art. Cramer automatically controlled humidity by a system which depended upon the relation between the wet- and dry-bulb temperatures. This was applied to the humidifying spray heads located in the room. Carrier devised the "dew point control," an improved form of air washer which not only brought the air to saturation, but also controlled automatically the temperature of such saturation, thus determining the moisture content of the air supplied.

**Types of Apparatus.**—Of the two main types of humidifiers, the direct spray type, which provides for the atomization of the water and its introduction directly into the room, is made in relatively small sizes. The nozzles or distributors are placed just below the ceiling, and provide for humidifying only. The saturated air type, on the other hand, introduces large volumes of saturated air at the required temperature.



In the conditioning chamber this air is brought into intimate contact with water finely divided by spraying through special nozzles under moderate pressure. All of the free particles of water are then removed by an eliminator, which usually consists of a series of specially formed baffle plates on which all free particles of moisture are caught, leaving the air saturated but free of all suspended water particles. The spray water may be heated or cooled, and the temperature of the saturated air may be modified before passing it into the room at the theoretic dew point.

When it is desirable to remove dust, soot and pollen from air, several types of filters may be employed. The most general types are composed of frames packed with fibrous glass, steel wool or similar materials. These may be covered with a viscous oil to hold the particles of dust more firmly. Special filter paper, arranged in V's for greater surface, is also employed. Electrostatic precipitators are installed in many large air-conditioning systems. Where dust particles of the smallest sizes must be removed, a special filtering medium of asbestos-bearing paper, closely pleated and completely sealed at the edges to a frame, is used.

Thermostats usually control the temperature automatically, either by admission of steam or hot water to the air heaters or by regulating the supply of cold, dehumidified air. Hygrostats control the humidity by regulating the air dew point, by varying the air volume or by on-and-off operation of the direct sprays.

After air conditioning of small shops, restaurants and other places had become general by mid-20th century, air-conditioning units assembled at the factory were developed. These are complete with fans, heaters, cooling coils and filters enclosed in a cabinet. The development of safe refrigerants also made it possible to include the compressor and condenser within the cabinet or to install them in some near-by place.

The quantity of moisture which may remain in the vapour state in a unit volume of space is dependent only upon its temperature. The saturation pressure of water vapour is approximately doubled for each 20° F. rise in temperature; *i.e.*, the maximum vapour pressure increases approximately in a geometric ratio for equal increments of temperature. The relation of the weight of water vapour in the atmosphere to the weight of air varies approximately in accordance with Dalton's law of partial pressures. When

BY COURTESY OF COOLING AND AIR CONDITIONING CORPORATION

DESIGN OF AIR CONDITIONING APPARATUS FOR LARGE BUILDING

water is brought into contact with unsaturated air it evaporates If the air is the sole source of heat necessary to produce evaporation, an eventual equilibrium saturation temperature is established depending on the initial air temperature and its initial degree of saturation. The reduction in the sensible heat of the atmosphere is equalled by the latent heat of the acquired water vapour; the total heat remains constant. The equilibrium temperature of evaporation is observed with practical accuracy by a wet-bulb thermometer. The general formula based upon this heat balance was stated in W. H. Carrier, "Rational Psychrometric Formulae," *Trans. A.S.M.E.*, vol. xxxiii.

When unsaturated air is passed through an air washer and brought to saturation without changing the temperature of the spray water, it will be cooled to the temperature of evaporation (substantially, to the wet-bulb temperature of the entering air). For example, when the outside air is at 95° F., the average wet-bulb temperature will be approximately 75° F. and the air passing through a spray humidifier will be cooled to substantially 75° F. This method of cooling is especially valuable in textile mills and tobacco factories where the increased humidity as well as the lower temperature is desirable.

The temperature of evaporation is independent of the actual rate of evaporation. The rate of evaporation of water into air is dependent upon the air velocity over the water surface and upon the difference in vapour pressure existing between the water and the air. The determinations of these relationships have important applications in the drying of materials in air.

**Regain.**—The ratio of moisture content to the weight of dry material is technically termed regain and is characteristic of most organic materials. The regain for various materials varies widely, each having its own moisture of equilibrium depending principally on the relative humidity of the surrounding air and to a slight extent on the temperature. The amount of regain varies with the relative humidity. Materials such as natural silk, wool, cotton and synthetic yarns are sold on the basis of standard regain. These materials are finally processed in an atmosphere having a relative humidity corresponding to the standard regain.

**Comfort.**—The relation of moisture, heat and air motion to human comfort and physiological reactions was determined by research. These data were plotted as effective temperature lines of equal comfort sensation for different combinations of temperature, humidity and air motion. Complete air conditioning is necessary for comfort. Temperature control alone is not sufficient since humidity is important.

**Residences.**—During the heating season, the humidity within residences becomes very low This is especially true in homes with open fireplaces With low humidity, dust particles float in the air and are augmented by brittle fibres from clothing, carpets, books, etc. Approximately three-fourths to one gallon of water per 24 hr. evaporated per room is necessary to raise the humidity from 15% to 35% or 40%. Excessive humidity may cause condensation and dripping from the windows.

Humidifiers are built into many hot air central heating systems Complete year-around air conditioning units with heating and mechanical cooling have been installed in many homes Factory-assembled, single-room cooling units as well as humidifying units are available, and with steam or hot water heating systems an evaporating pan can be set in the floor.

**AIRCRAFT CARRIERS.** With the exception of the amphibious craft developed in World War II, aircraft carriers represent the newest development in naval design. From the first experimental types built by both the United States and Great Britain late in World War I or soon thereafter, the carrier rapidly evolved into the queen of the battle line around which the U.S. navy built the fast carrier striking forces which swept Japanese air power from the skies and was a vital factor in winning the war in the Pacific.

Naval experiments with aircraft as a means of providing eyes for the fleet commenced early in the 20th century. The first flight of an aircraft from a U.S. naval vessel took place on Nov. 14, 1910, when Eugene Ely flew a Curtiss plane from a platform built on the bow of the cruiser "Birmingham," in Chesapeake bay. In January of the following year, in San Francisco, the same pilot landed a plane on a landing platform built on the stern of the U.S.S. "Pennsylvania" Ropes, stretched laterally across the landing platform, every three feet, had a 50-lb sand bag secured to each end, and were supported at a sufficient height from the deck to permit a hook on the plane to engage them. As the landing plane moved over the deck, it picked up an additional 100-lb. drag every three feet, thus being brought to a stop after travelling only a little more than half the length of the 120-ft. platform.

Experiments with shipboard aircraft were being carried out by Great Britain at approximately the same time, and in 1912 Commander C. R. Swanson flew a plane off H.M.S. "Hibernia." The following year the British flew seaplanes off the cruiser "Hermes," although the launching arrangement of small wheeled trucks supporting the plane resembled a catapult more than a flight deck. Three years later, the British completed a 250-ft. flight deck on the Cunard ship, "Campania," from which seaplanes were hoisted over the side into the water. While only one plane was flown off this model, the "Campania" introduced one feature common to all carriers since that time—an elevator which moved planes from the flight deck to a hangar space below, and brought them up again when flight operations were planned.

During the same period, tests were conducted with catapult launching of planes. A plane piloted by Theodore G. Ellyson was catapulted from an experimental model built at Annapolis, Md., in Nov. 1912, and in 1915 Comdr. Henry C. Mustin became the first person to make a catapult flight from a U.S. naval vessel when he was catapulted from the "North Carolina" in a Curtiss AB-2 flying boat. The U.S. cruisers "Seattle" and "Huntington" were fitted with catapults in 1916, and in 1917 these devices were capable of launching twin-float R-6 torpedo planes weighing 5,500 lb. The fact that such planes carried two 50-lb. bombs

indicated that naval minds, early alert to the possibilities of aerial reconnaissance, had also seized on the offensive uses of ship-borne planes. It is this feature of supplying wings to carry bombs and torpedoes to targets hundreds of miles away which eventually made the carrier the potent weapon it has become.

Actual operations of ship-borne planes during World War I were of slight importance. The U.S. cruiser "Huntington" carried catapult planes as submarine protection on convoy duty to Europe but the planes were not tried The British employed as many as four seaplane tenders during World War I; one was sunk, and one accompanied the British fleet when it met the German high seas fleet in the battle of Jutland, but was unable to provide the aerial observation of German fleet movements which could have given the British a decisive victory.

Profiting by this experience, the British completed, in 1918, a 300-ft flight deck on the "Furious," with no obstructions to hamper flight operations. In July of that year this ship made the first carrier raid in naval history by approaching to within 80 mi. of the German Zeppelin base at Tondern, from which point six Camels were launched in a foray which resulted in the destruction of the Zeppelins L54 and L60. With the Armistice, Britain announced the first flush deck carrier, "Argus," which featured a temporary "island" from which ship control and flight operations were directed, and the aircraft carrier as a type was established.

The first United States carrier, which began operations in 1922 was the "Langley," converted from the collier "Jupiter." (Long known as the "Covered Wagon," this ship was later converted to a seaplane tender which the Japanese sank off Java in 1942.) Five years later, the 33,000-ton giants "Lexington" and "Saratoga," built on battle cruiser hulls scrapped by the Washington naval treaty, joined the fleet, and in 1934, with the commissioning of the "Ranger," the U.S. navy had its first carrier built as such from the keel up. In the next 15 years more than 150 carriers of all types were built, either for use by the U.S. navy or for transfer to other nations.

**Carrier Aviation.**—Fleet employment of aircraft carriers covers two uses: as a fast striking force, and as an escort force. As the two terms imply, the functions are widely different and are usually performed by different classes of carriers.

The fast carriers, used both for offensive and defensive operations, observations of enemy fleet movements and shipping, and strikes against beach head targets, are primarily an offensive weapon. Built to provide mobility and flexibility of operation combined with strong aerial power and heavy defensive armament, the fast carriers are able to take aerial control of great sea areas and to harass and destroy enemy forces which may threaten friendly combatant fleets, merchant shipping or amphibious operations.

Fast carriers in 1950 were of two types, one carrying about 100 planes and the smaller, but equally fast, 33-plane ship. Fighter, dive bomber and torpedo bomber squadrons were organized in carrier air groups, whose operations were highly co-ordinated. Specialized groups consisting of night fighters and high-speed photo reconnaissance planes were also carried by fast carriers.

Wartime operation of such ships involved the task group of three to five carriers, supported by several battleships and cruisers and several divisions of destroyers, under one command. The fast carrier task force, such as task force 58 was composed of from two to five task groups. The striking power of such a force is illustrated by the fact that the first air assault on the Philippines in Sept. 1944 included 730 carrier planes, the task force which supported the Leyte landings a month later carried 1,060 planes and when task force 58 raided the Japanese home islands in Feb. 1945 the component carriers were able to put 1,220 planes in the air.

Escort carriers are slower, smaller ships, carrying about 30 planes, including fighters and torpedo bombers. The escort carriers, when organized as a force, provided air and anti-submarine defense for invasion convoys and beach head areas, and furnished aerial support for invasion troops until such time as conditions permitted the employment of land-based planes. Usually four to seven such carriers, with about twice as many escorting destroyers were assigned to support amphibious operations, but these carriers did operate individually in certain phases of anti-submarine warfare and escort duties.

**Tactical Effectiveness of Carriers.**—Any discussion of the value of the carrier in fleet operations must be based on the assumption that the term carrier includes such a ship with her aircraft embarked in fighting readiness. The first step in winning control of the sea is to take control of the air above it, and the carrier's high mobility permits it to be quickly placed in the area where air control is desired, while its offensive power, figured in aircraft, enables it to take control of the air in the face of the most persistent and continued resistance.

An early example of the value of air control was the German loss of the "Bismarck" in 1941, when the presence of H M S "Victorious" and "Ark Royal" allowed the British to put up sufficient planes to slow her to the point where battleships could close in for the kill. Later, in Dec. 1941, through lack of aerial control, Britain lost the "Prince of Wales" and "Repulse" to Japanese aircraft in the South China sea in an engagement lasting only two hours. Again, although this action took place in the straits of Dover within range of hundreds of R A.F. land-based planes, Britain lost an opportunity to sink the German "Gneisenau," "Scharnhorst" and "Prinz Eugen" because the Germans maintained aerial control of the immediate area with a heavy cover of fighters.

A special factor in control of the air is the ability to exercise control at all times, as was learned by the United States in 1943

*Aircraft Carrier Losses in World War II—All Nations*

| Name | Tonnage | Date | Place | Cause |
|---|---|---|---|---|
| UNITED STATES | | | | |
| Lexington | 33,000 | May 8, 1942 | Coral sea | Fire—sunk by U S. |
| Yorktown | 19,900 | June 7, 1942 | Midway | Submarine torpedoes |
| Wasp | 14,700 | Sept 15, 1942 | Solomons | Submarine torpedoes |
| Hornet | 19,800 | Oct 26, 1942 | Santa Cruz I | Fire—sunk by U S |
| Liscome Bay | 6,730 | Nov 24, 1943 | Tarawa I | Submarine torpedoes |
| Block Island | 6,730 | May 29, 1944 | Atlantic O | Submarine torpedoes |
| Princeton | 11,000 | Oct 24, 1944 | Leyte gulf | Damaged by Japanese shore-based aircraft—sunk by U S |
| Saint Lo | 6,730 | Oct 25, 1944 | Leyte gulf | |
| Gambier Bay | 6,730 | Oct 25, 1944 | Leyte gulf | by surface ships |
| Ommaney Bay | 6,730 | Jan. 4, 1945 | Lingayen gulf | Japanese aircraft |
| Bismarck Sea | 6,730 | Feb. 21, 1945 | Iwo Jima | Japanese aircraft |
| GREAT BRITAIN | | | | |
| Courageous | 22,500 | Sept 17, 1939 | Atlantic O | Submarine torpedoes |
| Glorious | 22,500 | June 8, 1940 | Off Norway | Surface action |
| Ark Royal | 22,000 | Nov. 14, 1941 | | Submarine torpedoes |
| Audacity | 5,537 | Dec 21, 1941 | | Submarine torpedoes |
| Hermes | 10,850 | April 9, 1942 | | Japanese aircraft |
| Eagle | 22,600 | Aug 11, 1942 | | |
| Avenger | 12,000 | Nov. 15, 1942 | Gibraltar | |
| Dasher | 12,000 | March 27, 1943 | Firth of Clyde | |
| Nabob | 13,785 | Aug 22, 1944 | North Cape | |
| Thane | 13,785 | Jan 15, 1945 | The Clyde | |
| JAPAN | | | | |
| Shoho | 12,000 | May 7, 1942 | Coral sea | U S carrier planes |
| Hiryu | 17,500 | June 4, 1942 | Midway | U.S carrier planes |
| Akagi | 36,000 | June 4, 1942 | Midway | U S carrier planes |
| Kaga | 35,000 | June 4, 1942 | Midway | U S carrier planes |
| Soryu | 17,500 | June 4, 1942 | Midway | U S carrier planes and submarines |
| Ryujo | 8,500 | Aug 24, 1942 | Solomons | U S carrier planes |
| Chuyo | 20,000 | Dec. 4, 1943 | Off Honshu | U S submarine torpedoes |
| Shokaku | 30,000 | June 19, 1944 | Off Yap I | U S submarine torpedoes |
| Taiho | 31,000 | June 19, 1944 | Off Yap I. | U S submarine torpedoes |
| Hitaka. | 28,000 | June 20, 1944 | Philippine sea | U S carrier planes |
| Otaka | 20,000 | Aug 18, 1944 | Luzon | U S submarine torpedoes |
| Unyo | 20,000 | Sept. 16, 1944 | China sea | U S submarine torpedoes |
| Zuiho | 12,000 | Oct 25, 1944 | Luzon | U S carrier planes |
| Zukaku | 30,000 | Oct. 25, 1944 | Luzon | U S carrier planes |
| Chitose | 11,000 | Oct. 25, 1944 | Luzon | U S carrier planes and surface craft |
| Chiyoda | 11,000 | Oct 25, 1944 | Luzon | U S. carrier planes |
| Jinyo | 21,000 | Nov. 17, 1944 | Yellow sea | U S submarine torpedoes |
| Shinano | 59,000 | Nov. 29, 1944 | Off Honshu | U S submarine torpedoes |
| Unryu | 18,500 | Dec. 19, 1944 | China sea | U.S submarine torpedoes |
| Kaiyo | 17,000 | July 24, 1945 | Japan | U S carrier planes and Army |
| Amagi | 18,500 | July | Japan | U S |

Note: All U S carriers sunk by Japan with exception of "Block Island", all British carriers sunk by Germany and Italy with exception of Illustrious, all Japanese carriers sunk by U S. losses from various official U S navy reports, also on British losses from *Jane's Fighting Ships, 1944-45*, Sampson Low, Marston & Co Ltd. (London, 1945), right on Japanese losses from U.S. Joint Army-Navy Assessment Committee, *Japanese Naval and Merchant Shipping Losses During World War II By All Causes* (Feb. 1947).

when the Japanese began to stress night torpedo attacks. The U.S. navy equipped carrier-type Hellcats and Corsairs with instruments for night fighting, and was conducting effective night-fighting operations from all carriers before the army land-based Black Widow night fighter reached the theatre. Night-fighting Hellcats alone accounted for 163 enemy planes with only three losses.

Possibly the best indication of the tactical effectiveness of carriers lies in the figures on Japanese shipping losses prepared by the Joint Army-Navy Assessment committee, on the basis of official Japanese documents. These figures, covering the entire period of hostilities, and compiled for all Japanese naval vessels and merchant ships of more than 500 tons, reveal that U.S. forces sank a total of 2,728 ships with a tonnage of 9,736,068. More than half the total was accounted for by U.S. submarines, but of the remainder, 520 ships displacing 2,101,477 tons were sunk by carrier aircraft. In addition, carrier aircraft in combination with other planes or vessels sank another 35 ships totalling 210,085 tons.

**Carrier War in the Pacific.**—Hostilities between the United States and Japan commenced with a well-planned and -executed Japanese carrier raid on Pearl Harbor the morning of Dec. 7, 1941, resulting in the complete loss of two U.S. battleships and immobilization of others for many months. Emphasis on carrier warfare was indicated by the fact that attacking Japanese pilots expected to find two U.S. aircraft carriers in the harbour and consequently pressed home a fierce attack on other ships which were in the usual carrier berths.

The next phase of the carrier war was the February to April series of diversionary raids by fast U.S. carriers in the Gilbert and Marshall Islands, Wake Island, Marcus Island and New Guinea, plus the famous Tokyo raid by Gen. James Doolittle leading a group of planes flown off the "Hornet." This phase was followed by the Coral sea battle which occupies a unique place in naval history in that it was the world's first major naval engagement in which opposing ships did not exchange a single shot.

In June 1942, U.S. and Japanese forces again met in the battle of Midway. While the United States lost one carrier, Japan lost four; this marked the first Japanese naval defeat in 350 years, ended its offensive action in the Pacific, and so reduced Japanese aerial power that its carriers were not again encountered in numbers for almost a year. During that time, U.S. carriers, in increasing numbers, continued strikes against enemy island bases, ending the year of 1943 with an 11-ship strike against the Gilbert and Marshall Islands.

Increased carrier warfare in 1944 resulted in 4 U.S. carriers being lost against 12 Japanese carriers sunk, and reached a culmination in the October battle of Leyte gulf, when U.S. carrier planes alone sank 4 Japanese carriers, 1 battleship, 2 light cruisers and 5 destroyers, besides assisting in the destruction of many others. At this point, the Japanese navy ceased to exist as a fighting force and control of the air passed to the United States.

Until the war ended, fast carrier striking forces ranged the western Pacific at will; in January they raided Formosa, Luzon, French Indo-China, Hong Kong, Canton, Okinawa and the Ryukyus; Tokyo was hit in February, the Inland sea in March and the China sea in April. Raids on the empire continued until the war was officially ended. In 44 months of carrier warfare, the United States lost 138,000 tons of carriers against 483,000 tons for Japan; for 451 carrier planes lost in air-to-air combat there were destroyed 6,444 Japanese planes in air combat plus 5,824 more destroyed on the ground.

**Postwar Carrier Disposition and Employment.**—With the cessation of hostilities in 1945, the immense carrier fleet of the U S. navy was no longer required, and approximately 75 carriers were placed in reserve in the "mothball fleets." This involved maintaining the ships in a state of preservation such that they might be quickly placed in operation again when needed Others, particularly those converted to naval use from merchant ship hulls, were sold as being in excess of naval needs, and some of these again were converted for various commercial purposes.

Of the carriers in active service with the fleet, some were undergoing extensive modifications to fit them for use with heavier and larger planes in use, such as the Douglas Skyraider, with a wingspread of 50 ft. and weight of more than 10 tons, and the Martin Mauler, of similar size but weighing more than 12 tons loaded.

While continuing the tactical development of carrier aviation, carriers in commission also served as a testing ground for evaluation of new types of planes, and as a means of keeping in training the thousands of naval reserve flight personnel

Postwar carrier operations also stressed the employment of carriers in "hunter-killer teams," an exclusive development of anti-submarine warfare, in which several destroyers act as the hunter of a submarine while the carrier planes perform the actual kill.

**Carrier Description.**—Since an aircraft carrier's one purpose is to carry planes, the landing platform, or flight deck, is the most outstanding feature of the ship. Varying in width from more than 60 to more than 100 ft., and in length from 500 ft. to almost 900 ft., it provides a miniature airport on which planes land, are fueled and armed, and take off A series of steel cables extend athwartships over the after portion; these are lifted mechanically when a plane lands, and as a hook dropped from the plane's tail engages one of the arresting cables, hydraulic brake drums on either end deccelerate the plane to a stop. In take-off, planes taxi off the forward end of the deck until airborne, although catapults built flush in the deck can be used when necessary, and jet-assisted take-offs were used for particularly heavy planes, such as the Martin Mariners flown off a carrier in Operation "Highjump" in Antarctica in 1947.

One or more elevators carry planes to and from the hangar deck, an open space almost as wide and long as the flight deck, where planes are parked when not immediately needed. As many as 200 planes can be carried in hangar and flight deck stowage by large carriers in "ferry" service. In the great hangar deck space, crews load bombs, torpedoes and ammunition, and gasoline into the planes, and perform overhaul and repair work as required. The hangar deck is, essentially, the true upper deck surface of the ship; beneath it are the living quarters, shops, storerooms, and engineering spaces common to all ships. Many carriers are, under the skin, sisters to various other types of ships; the "Independence" class carriers were built on the hulls of "Cleveland" class cruisers; the "Sangamon" class carriers were converted from oil tankers, and the "Bogue" class carriers were converted from maritime commission $C_3$ hulls.

In order to attain their high speed, carriers are built with little or no armour, sacrificing such equivalent weight for the flight deck and an immense load of gasoline, bombs, torpedoes, fuel oil, spare parts and the stores and provisions with which to maintain as many as 3,000 men for an extended period. Some protection is offered by 5-in. guns and the many smaller automatic guns, but the carrier's chief defense is her speed and the firepower of such of her own planes as can be employed in defensive operations.

The vital nerve centres of a carrier are centred in the island, the only part of the superstructure extending above the flight deck. Here the ship is controlled and operated, and here all flight operations are handled. The island is located on the right-hand side of the flight deck in all aircraft carriers, except for the Japanese "Kaiyo" and "Hosyo," which were built without islands. Due to the din of dozens of motors connected with any flight operation, spoken conversation is practically impossible, and various hand signals are used by plane crews and plane handlers, although orders from the island can be given to the flight deck with a "bull horn," an electrical amplifier capable of magnifying the voice hundreds of times. To eliminate confusion among the many men working on the flight deck during operations, the men in each "gang" performing a specific task wear jerseys of a distinctive colour.

The actual landing of the planes aboard the carrier is under the control of one officer stationed at the after end of the flight deck. Highly experienced in the operation of carrier aircraft, he watches the approach of each plane, indicating to the pilot through a series of hand signals the proper moves to make in bringing the plane in to a landing. At any time the landing officer judges the approach unsafe, he waves the plane off and the pilot withdraws

into the landing circle of other planes to await his turn to come in for another landing

**Types of Carrier Planes.**—Carrier planes in 1950 were of three major types fighters, dive bombers, and torpedo planes Fighter planes, designed for combat with enemy aircraft, were armed with machine guns and rockets; these with bombs, were also used against ships and land targets. Wartime carrier fighters were either Corsairs, Wildcats or Hellcats; types employed later included the jet-engined Cutlass and Sky Knight.

Dive bombers, as the name implies, dropped their bombs at the end of a dive, from extremely low levels, thus obtaining great accuracy. Such attacks were usually made in co-ordination with fighters and torpedo bombers as a triple threat offense. The early World War II dive bomber was the Douglas Dauntless, followed by the Curtis Helldivers. Torpedo bombers were Douglas Devastators and later, Grumman Avengers, carrying either a torpedo, a ton of bombs, depth charges or mines. Postwar planes of this class, classified as "attack planes," included the Douglas Skyraider and Martin Mauler. The twin-engined Lockheed Neptune patrol plane was also being modified for carrier operations.

(A. S. L.)

**AIRD, SIR JOHN,** 1ST BART. (1833–1911), British engineer, was born in London Dec. 3, 1833, the only child of John Aird, contractor for gas and water plants. He joined his father's business at 18, and was entrusted with the removal of the Crystal Palace buildings from Hyde Park and their re-erection at Sydenham.

He took part in many enterprises, such as the Hampton and Staines reservoirs, the waterworks of Amsterdam, Copenhagen, Moscow, Bahia, Pará, Calcutta, Simla and Berlin, and later (in the joint firm of Lucas and Aird, afterward John Aird and Co.) St. John's Wood railway, Hull and Barnsley railway and docks, the W. Highland railway and the great Aswan dam across the Nile. He represented N. Paddington in parliament as a Unionist from 1887 to 1905, and was its first mayor in 1900. In 1901 he was created a baronet. He made a fine collection of pictures by British painters, the illustrated catalogue to which was printed in 1884. He died at Beaconsfield, Bucks., Jan. 6, 1911.

**AIRD,** THOMAS (1802–76), Scottish poet, and journalist, was born at Bowden, Roxburghshire, on Aug. 28, 1802, and died at Dumfries on April 25, 1876. He was educated at Edinburgh university, where he made the acquaintance of Thomas Carlyle and James Hogg, and he decided to devote himself to literary work. He published *Martzoufle, a Tragedy, with other Poems* (1826), a volume of essays and a long narrative poem in several cantos, *The Captive of Fez* (1830).

For a year he edited the *Edinburgh Weekly Journal,* and for 28 years the *Dumfriesshire and Galloway Herald.* In 1848 he published a collected edition of his poems, which met with much favour. Carlyle said that he found in them "a healthy breath as of mountain breezes." Among Aird's other friends were Thomas de Quincey, John Gibson Lockhart, Arthur Penrhyn Stanley (afterwards dean of Westminster) and William Motherwell.

*See* a "Life" by J. Wallace prefixed to the 5th edition (1848) of his *Poems.*

**AIRDRIE,** a large burgh of Lanarkshire, Scotland. Pop. (est. 1938) 28,134. Area, 3.23 sq.mi. It is 11 mi. E. of Glasgow by the Scottish region railway, and connects with Glasgow by the Monkland canal, as well as by the Scottish region railway via Coatbridge and Whifflet. The canal (constructed 1761–90) connects with the Forth and Clyde canal near Maryhill. Airdrie was a market town in 1695; its later prosperity was due to coal and iron beds. Industries are boilermaking, sanitary engineering, iron and brass founding, general engineering, railway carmaking and cotton manufacturing.

The burgh was the first town in Scotland to adopt the Free Library act. Airdrie unites with Coatbridge in sending one member to parliament. The parish of New Monkland, in which Airdrie lies, was formed (with Old Monkland) in 1640 out of the barony of Monkland, land granted by Malcolm IV to the monks of Newbattle.

**AIRE,** a town of north France, on the Lys, in the department of Pas-de-Calais, 12 mi. S.S.E. of St. Omer by rail. Pop. (1946) 5,194. The town lies in a low and marshy situation at the junction of three canals. In the middle ages Aire belonged to the counts of Flanders, and a charter (1188) is still extant. It was given to France by the Peace of Utrecht (1713).

The church of St Pierre (15th and 16th centuries) shows three stages of Gothic architecture. The hôtel-de-ville is 18th century. Aire has considerable trade in agricultural produce In World War I it was one of the headquarters of the British army (1917–18).

**AIRE,** a town of southwest France, in the department of Landes, on the Adour, 22 mi S E of Mont-de-Marsan on the railway between Morcenx and Tarbes. Pop. (1946) 2,974 Aire (*Atura, Vicus Julii*) was the residence of the kings of the Visigoths, one of whom, Alaric II (*q v* ), there drew up his famous code

It is the seat of a bishopric dating from the 5th century, and has a cathedral of the 12th century and an episcopal palace of the 11th, 17th and 18th centuries. Both have undergone frequent restoration. They are surpassed in interest by the church of St Quitterie in Mas d'Aire, the suburb southwest of the town The latter is a brick building of the 13th and 14th centuries, with a choir in the Romanesque style, and a fine western portal which became much disfigured. The crypt contains several Gallo-Roman tombs and the sarcophagus (5th century) of St. Quitterie

**AIR ENGINE.** The practical drawbacks to employing air as the expanding substance of a heat engine are so great that its use has been very limited. Such attempts as have been made to design air engines on a large scale have been practical failures, and are now interesting only as steps in the historical development of applied thermodynamics. In the form of domestic motors, air engines had some application, prior to the development of the internal combustion engine and the extended use of electricity. The type survives in a few motors of very small power. One of the chief practical objections to air engines is the great bulk of the working substance in relation to the amount of heat that is utilized in the working of the engine. Another is the difficulty of getting heat into the working air through the walls of the containing vessel.

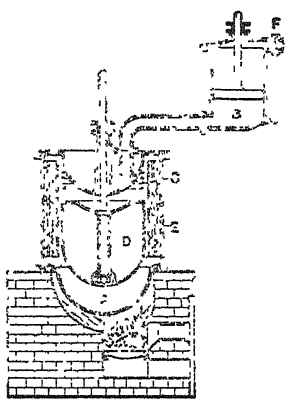

FIG 1.—STIRLING'S AIR ENGINE

The working parts shown are:

A. Externally fired heating vessel
3. Working cylinder
C. Cooling pipes
D. Displacer
E. Regenerator
F. Connecting flange to another heating vessel

Air takes up heat from such a surface with much less readiness than does water. The waste of heat in the chimney gases is accordingly greater; and further, the metallic shell is liable to be quickly burned away as a result of its contact at a high temperature with free oxygen. The temperature of the shell is much higher than that of a steam boiler, for in order to secure that the working air will take up a fair amount of heat, the upper limit to which its temperature is raised greatly exceeds that of even high-pressure steam.

A form of air engine invented in 1827 by the Rev. R. Stirling is of special interest as embodying the earliest application of what is known as the "regenerative" principle, namely, the principle that heat may be deposited by a substance at one stage of its action and taken up again at another stage with but little loss, and with a great resulting change in the temperature of the substance at each of the two stages in the operation.

The principle has since found wide application in metallurgical and other operations. In any heat engine it is essential that the working substance should be at a high temperature while it is taking in heat, and at a relatively low temperature while it is rejecting heat.

An attempt to develop a powerful air engine was made in the

ment of the atomic bomb, with its infinitely great destructive power as compared with ordinary high explosive, was likely to have the effect of cutting down both the number and size of bombers employed.

It might well be that the air forces which had been developed from the flimsy reconnaissance machines of 1914 to the jet fighters and superheavy bombers were already obsolescent a few years after World War II, and that the next air weapons might be pilotless craft controlled from the ground and carrying destructive loads more powerful than anything yet envisaged. In that event, the whole theory and practice of warfare might change once again. (D. Cr.)

## UNITED STATES

When the United States entered World War I, little had been done toward giving the aviation section of the army's signal corps either adequate equipment or trained personnel, and its record of participation in the punitive expedition into Mexico (in its only previous combat operation) was one of dismal failure. In 1917 congress authorized an increase in personnel and appropriated $640,000,000 for procurement of aircraft and for the support of the augmented aviation section, which now expanded rapidly from a personnel strength of 131 officers (of whom 78 were pilots) and 1,120 enlisted men in 7 squadrons (in April 1917) to 20,000 officers, 600 cadets and 164,000 men in 7 squadrons (in Nov. 1918). Aviation served successfully as the "eyes of the armies" as hostilities deteriorated into the long stalemate of trench warfare. A force of 1,481 planes—U.S., British and French—under the command of Col. William L. ("Billy") Mitchell took part in the St. Mihiel offensive of Sept. 1918, without producing decisive action. But World War I gave early training to future air leaders, revealed the potentialities of aviation for strategic as well as tactical reconnaissance, hastened the technical developments of aeronautics and pointed the way to the future use of air power in strategic bombardment.

The Army Reorganization act of 1920 established the renamed air service as a separate and co-ordinate arm of the army with an authorized strength of 1,516 officers and 16,000 enlisted men. The air service now concentrated on the progressive development and improvement of planes and motors built according to new and better designs. Experiments were made with the use of dirigibles, but they did not prove successful. Notable early records for distance, speed and endurance were achieved

The Air Corps act of 1926 gave the air service a new name, and by provisions affecting personnel and procurement sought "to provide more effectively for the national defense by increasing the efficiency of the Air Corps." On June 20, 1941, the army air forces was established and—particularly as a result of reorganization announced March 2, 1942—achieved *de facto* autonomy, absorbing for all practical purposes the army air corps.

World War II saw the development of the use and the maturing of the strategic concept of air power. Tactical air power co-operated with the army and the navy to win victories in the invasion of North Africa in Nov. 1942, as it was to do later in the invasion of Normandy in the summer of 1944. But independent action of the A.A.F. (in co-operation with the R.A.F.) in long-range, strategic bombardment (chiefly by B-17s) did much to destroy and dislocate the German military, industrial and economic system and to undermine the morale of the German people to the point where their capacity for armed resistance was fatally weakened. Particularly notable was the destruction of the German fighter defense, beginning in July 1943 and culminating in the "Big Week" of Feb. 20, 1944, when six days of perfect flying weather permitted 8th bomber forces almost all on the widely-dispersed German air-frame factories and assembly plants. The German aircraft industry never fully recovered from the blow, and the Allies controlled the air over Europe during the remaining 14 months of the war.

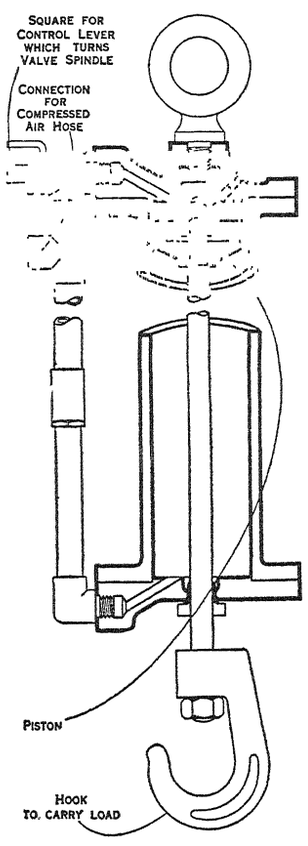
In the Pacific the A.A.F. won its initial victories in the China-Burma-India theatre giving substantial protection against Japanese forces and disrupting the Japanese shipping and railways. It transported men and supplies for all U.S. forces, and in its flight from bases in India over the "Hump" of the Himalaya to China performed a logistic air feat previously unparalleled, that kept China in the war. Co-operating with navy and marine air forces, it assured air superiority in the push toward Okinawa, and finally, when B-29s dropped single atomic bombs on Hiroshima and Nagasaki on Aug. 6 and 9, 1945, it deepened the conviction of the Japanese people that surrender was inevitable.

After the surrender of Japan the A.A.F. shrank rapidly from its wartime peak of 2,400,000 men and officers and 80,000 planes to a low point of 303,614 military personnel in May 1947. Hasty demobilization weakened the training facilities of the air force and reduced the force to such a low state in operational efficiency that there was deep concern for its capabilities. Anticipating the eventual enactment of legislation to establish an autonomous air force within a unified defense establishment and taking heed of lessons learned during the war, the air force reorganized its structure into functional commands to replace the previous organization based on geographical or area responsibility, or on the type of aircraft employed, and reorganized its headquarters functionally as well. The command structure that became effective June 11, 1946, was retained when autonomy was achieved, and the United States air force came into existence Sept. 18, 1947.

Of the three military services, the air force at mid-century had primary interest in operations in the air and had the responsibility, assigned by the joint chiefs of staff, of being organized, trained and equipped for prompt and sustained combat operations. There were two combat commands, eight supporting commands (which for the most part performed functions implicit in their names) and five commands overseas. The continental air command combined the former air defense command and tactical air command into a continental defense command, while the strategic air command trained primarily for long-range operations in any part of the world at any time, either independently or in co-operation with land and naval forces. The air matériel command, the air proving ground and the air training command lent direct support, while the Air university provided the training of staff and command officers. The military air transport service, a joint operation with the navy for which the air force had responsibility, provided air transportation for personnel and cargo of all agencies of the department of defense. The air force special weapons command was responsible for the service and development testing, within the field of air force interest and responsibility, of equipment and techniques relating to atomic energy. The research and development command (established Jan. 1950) had supervision of all U.S.A.F. field activities supporting research and development. The headquarters command supported the air staff.

The Alaskan air command and the Caribbean air command remained essential to hemispheric defense. The United States air forces in Europe and the far east air forces had occupational duties. The 3rd air division, raised to command status in Jan. 1949 with headquarters in England, supported air force activities overseas.

The necessity of performing the air lift supply of about 2,250,000 people in Berlin from June 26, 1948, to Sept. 30, 1949, proved a diversion from the air force's main task of rebuilding operational effectiveness, but provided opportunities that in the end contributed notably to the development of techniques and to the refinement of the total operational activity. In the "Good Friday" lift of mid-April 1949, 12,941 tons of food, clothing, fuel and other supplies were flown in to the beleaguered city in 24 hr. Almost 2,500,000 tons of supplies were carried in the 15 months of air lift in an unexcelled air logistics feat.



The attention to research and development which had characterized U.S. military aviation from its inception in 1907 was considerably increased after World War II and led to the rapid development of jet and rocket air power; to development of the long-range intercontinental bomber, the B-36; to establishment of records for long-range, high altitude and speed flights; and to notable experiments with guided missiles, which had been only slightly developed at the close of World War II. Particularly significant as pointing the way to future experiments and developments, and use of air power, were the many flights of the X-1

research aircraft after Oct. 1947 at a speed hundreds of miles in excess of the speed of sound (760 mi per hour at sea level) and the flights of a C-54 transport aircraft across the Atlantic, under the control of a mechanical automatic "pilot," in the fall of 1947.

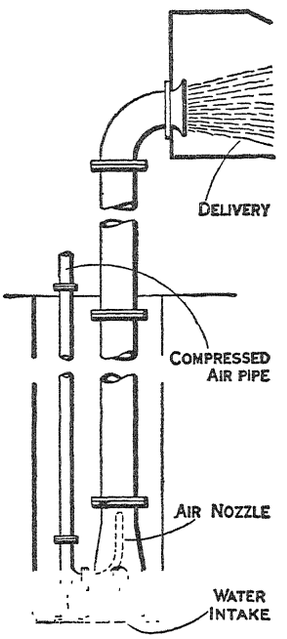
**AIR GAS:** *see* GASOLINE PRESSURE APPLIANCES.

**AIR GUN,** a gun in which the force employed to propel the bullet is the elasticity of compressed atmospheric air. It has attached to it, or constructed in it, a reservoir of compressed air, a portion of which, liberated into the space behind the bullet when the trigger is pulled, propels the bullet from the barrel by its expansion. The common forms of air gun, which are merely toys, are charged by compressing a spiral spring, one end of which forms a piston working in a cylinder; when released by a pull on the trigger, this spring expands, and the air forces out the bullet.

**AIR HOIST.** In factories and other places where a supply of compressed air is available, its use for operating lifting tackle is much favoured, because of the cleanliness, absence of noise and ease of connection with flexible hose. The direct hoist, raising a load 4 or 5 ft., and dealing with from 100 to 7,000 lb in different sizes, is the simplest. It comprises a cylinder, a piston, a rod attached thereto and carrying the lifting hook at the bottom and an operating valve, controlled by pendant chains. An eyebolt at the top affords means of suspension to a fixed beam, or a swinging jib, or to a trolley running on a girder, either stationary or forming part of a jib or travelling crane.

WORKING PARTS OF AN AIR HOIST

The hoist is suspended from the eye at the top and the load is slung on the hook. The piston is shown at the top of the chamber, it having been forced upward to the full length of its stroke by the pressure of the air from below



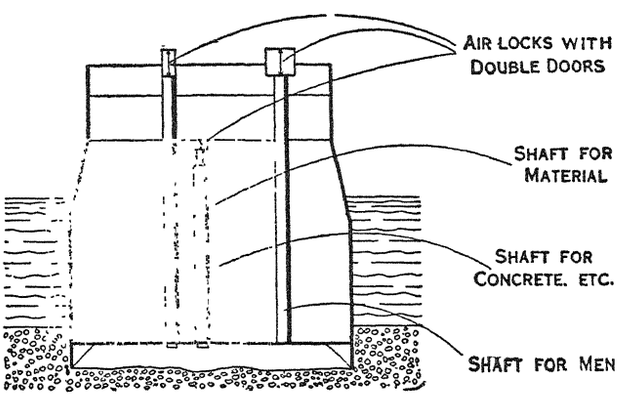
The hoist shown in the diagram is controlled by balanced pressure. The full air pressure of 100 lb. per square inch is maintained at the underside of the piston throughout all the operations of lifting, lowering and remaining stationary. For lifting, the attendant manipulates the valve so that air leaks off the top piston.

Another way of applying air power is to use a [illegible] valley block to which is [illegible] small pneumatic motor, the cylinders of which actuate connecting rods and so drive a crankshaft, this being geared to the rope drum in order to gain power. Loads up to ten tons can be lifted in this way.

For colliery service, another class of air hoist is built, a winch or haulage engine, the rope drum being driven through gears from a pneumatic motor. This is essential in circumstances where compressed air is the power supply in use. Some of the engines can be run either with air or steam.

**AIR LAW:** *see* AERIAL LAW.

**AIR LIFT,** a system of lifting liquids by compressed air without a pump. For artesian wells the method consists in carrying down a smaller air pipe either within the water delivery pipe or alongside it and connecting an air compressor. The compressed air forms with the water a mixture of lower specific gravity than the surrounding water in the well or bore hole, with the result that the mixture of air and water in the tube is forced by the weight of the surrounding water to the point of discharge (*see* figure). When the supply flowing into a well is not enough to give constant delivery, waste of energy may be avoided by a governor. Some air lifts yield as many as 285,000 gal. per hour per well. The Shone ejector, another form of air lift, is used for raising sewage and other liquids automatically from one or any number of points, and forcing to any spot desired. The difference between this and the well lift just described is that the liquid gravitates into a bell-shaped casting through an inlet pipe and rises until the vessel is nearly full. Then the air trapped at the top becomes slightly compressed and acts on a metal cup that lifts a valve and admits a supply of compressed air into the vessel. This drives the sewage out through an outlet pipe to reach a higher level or any distance away; a fresh supply enters through the inlet pipe which has been [illegible] during the discharge, and the cycle commences again.



THE OPERATION OF AN AIR LIFT

The diagram shows water being forced up from a well by compressed air. Although chiefly supplied to wells and for lifting sewage, the method can be also used for moving acids, sludges, slimes and heavier liquids

**AIR LIFT (BERLIN).** On June 26, 1948, an intensive air cargo operation was launched by the United States and Great Britain to offset a soviet land blockade of Berlin from western Europe. The blockade was aimed at wresting the western (U.S., British, French) sectors of Berlin from the control of the three western powers. It lasted 10½ months, to May 12, 1949, with a tapering off period ended Sept. 30. During the total period, the 2,500,000 inhabitants of the western sectors were supplied with 2,323,738 tons of food, coal, machinery and other necessities (1,783,826 tons by U.S. planes, 538,416 by British), at a cost, to May 12, of $170,000,000. The air lift was discontinued after the U.S.S.R. agreed to reopen land and rail communications to the city.

**AIR LOCK,** a steel-plated chamber provided in a tunnelling shield or a caisson (*q.v.*), to prevent the escape of compressed air during the passage of workers. The pressure in the caisson may be 25 to 30 lb. per square inch, though higher pressures have been used. A steel door at each exit of the lock provides for the

THE USE OF AIR LOCKS IN CONNECTION WITH A BRIDGE CAISSON

The usual air pressure in caissons is 25 to 30 lb. per square inch, and steel locks are provided for each shaft. Excavated material is raised by power and, at great depths, cages are used to bring workers to the surface. Under the high pressure, work becomes laborious, and every effort is made to minimize the worker's fatigue

safe passage of men or material, one being opened while the other is shut. There will be several locks in a tunnel shield and in some big caissons The diagram indicates the shape of a caisson, sunk to make the foundation for a bridge pier, two shafts for material and one for men being fitted The shaft down which concrete is shot has its airlock placed lower than those of the other shafts, because the concrete mixer happens to be located on the lower platform.

Air lock also means the trapping of air in a bend; *e.g.*, of a water or gasoline supply, stopping the flow

**AIR LOG** or **AIR DISTANCE RECORDER,** an instrument which measures the distance flown by an aeroplane relative to the air. It consists of two units: a transmitter, which is installed on a wing strut or in some other position on the aircraft where it receives undisturbed air, and an indicator, which is mounted on the instrument board. The transmission may be either pneumatic or electric.

The transmitter comprises an impellor or windmill, which revolves as the aircraft moves through the air, the number of revolutions being proportional to the air distance travelled. The motion of the impellor is reduced by gearing to actuate a valve or contact at a predetermined unit of distance, the resulting impulse of air or electric current operating a ratchet in the indicator. The latter unit is simply a counter. By properly relating the pitch of the impellor blades and the gearing, the instrument will record any unit of distance, such as geographic miles, nautical miles or kilometres. The instrument is rendered inoperative below a predetermined minimum speed, in the pneumatic type by relating the air pressure to the speed in such a way that operating pressure is not available below the minimum speed, and in the electric type by using a centrifugally controlled switch. This protection is necessary to prevent the operation of the air log by the wind, while the aircraft is on the ground. (C. H. C)

**AIR MASS,** (a) in physical meteorology, the term for unit of mass of the atmosphere passed through by the sun's rays in reaching from outside the atmosphere to the earth's surface. Air mass of value 1 is defined as the amount of air passed through by the vertical rays when the sun is in the zenith Then for lesser elevations of the sun above the horizon, the air mass *m* is nearly proportional to the secant of the sun's zenith distance, and may be described as the equivalent number of atmospheres of air mass 1 which the rays would pass through at any given solar elevation.

Tables of *m* values for various zenith distances are required for convenience in calculating the absorption of solar energy by the atmosphere. In order to avoid confusion with the expression *air mass* (*see* below) as used in synoptic meteorology, E. W. Woolard and I. F. Hand suggested the word *air path* for *m*

(b) In synoptic meteorology, *air mass* is the designation for a vast body of air in which certain physical properties—mainly those of special value in analysis for weather forecasting purposes —vary but slightly in the horizontal.

The basic properties of air masses which determine characteristics of the weather are the vertical distribution of temperature and moisture content. These properties determine the actual or [illegible] of clouds and precipitation. Two air masses of similar horizontal homogeneity and similar average temperature and moisture at the ground, may have very different vertical distribution of these properties. The practice of air mass analysis for weather forecasting therefore requires upper-air soundings to determine the vertical distributions, although it is possible to infer to some extent the latter from the conditions measured at or seen from the ground.

The origin and persistence of distinctive air masses are explained by the facts: (1) that there are certain large *source regions* of the earth's surface where conditions are sufficiently uniform so that the overlying air can acquire similar characteristics; *i.e.*, horizontal homogeneity, throughout the region; and (2) that the general circulation of the world's atmosphere has large-scale [illegible] that are more or less steady and permit the travel of the air masses over long distances without being dispersed into small eddy branches.

The primary source regions are the polar areas and the subtropical belts (around 10°–30° latitude). The middle latitudes are the scene of interactions between the polar and tropical air masses, which intertwine and over- or underrun one another in great spiral trajectories that constitute the travelling cyclones and anticyclones (*q.v.*).

Such interactions produce the major weather variations in these latitudes (*see* METEOROLOGY). There is a subsidiary class of source regions in middle latitudes where the effects of the prevailing difference in temperature between ocean and continent surfaces tend to transform originally polar or tropical air masses passing over them into subtypes with distinctive and important characteristics.

Thus polar (or tropical) maritime and polar (or tropical) continental air masses are created, which also may interact in cyclones and anticyclones as a result of the large-scale air circulation bringing them together. Near the coasts very rapid and striking transformations in air mass properties often take place, when for example, warm continental air moves onto cold ocean waters (in summer) or (in winter) cold continental air moves onto warm ocean waters; although such effects do not reach to very high levels in the atmosphere and are usually limited in area, locally they may play a dominant role in the weather.

Small-scale phenomena, such as sea and land breezes, mountain and valley breezes, may be considered as the result of contrasting local or pseudo air mass source regions

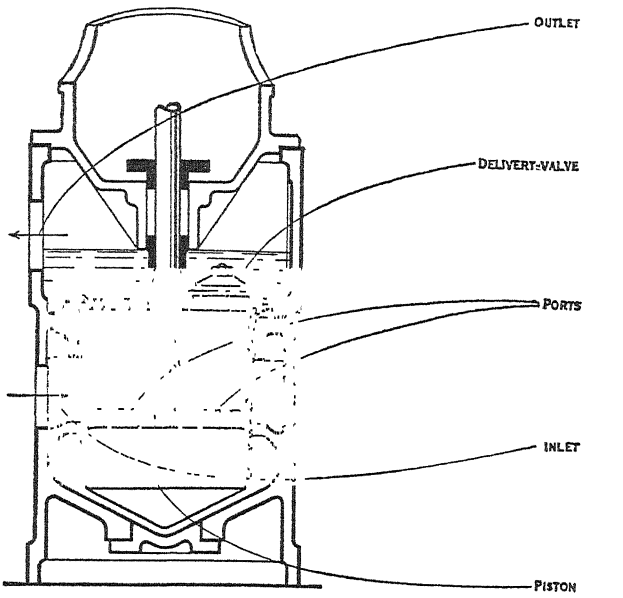
Although the air mass concept was recognized in a general way by H W. Dove and others before the middle of the 19th century, its practical significance in weather forecasting was first realized in 1917 by Norwegian meteorologists hard-pressed for a new technique to compensate for their lack of foreign weather reports withheld by the neighbouring warring nations. By 1923 it had been adopted by the weather services in Belgium and Germany; by 1930 in most advanced countries. It greatly improved accuracy of forecasting, but only for periods up to 24 or 36 hr. in advance, and clarified the understanding of many familiar weather phenomena.

The classification and detailed description of air masses are found in many modern standard treatises on meteorology (*see* especially H. C. Willett, *Descriptive Meteorology* [1944], pp. 183–224).

The classifications in use, however, are all based on properties important for forecasting temperature, clouds, rain, etc It would be possible to make other classifications based on properties more important for other problems. This may not be entirely necessary, in as much as many phenomena (optical, electrical, biological, etc.) are more or less strongly influenced directly or indirectly by the same properties on which the existing forecasters' classification scheme is based.

The development of an air mass climatology has been proposed. It would entail first a description of the climate which is peculiar to each air mass type and then a description of the climates of places or regions in terms of the occurrence of the various air masses.

It had not been demonstrated by 1947 whether such a method would contribute much new understanding of the climate. In general, the usefulness of the air mass concept is limited by the lack of absolute homogeneity within and the diffuseness of the transitions between the air masses as observed in nature. The identification of air masses can not be made rigorously and only a qualitative unanimity of opinion about it can be obtained among meteorologists.



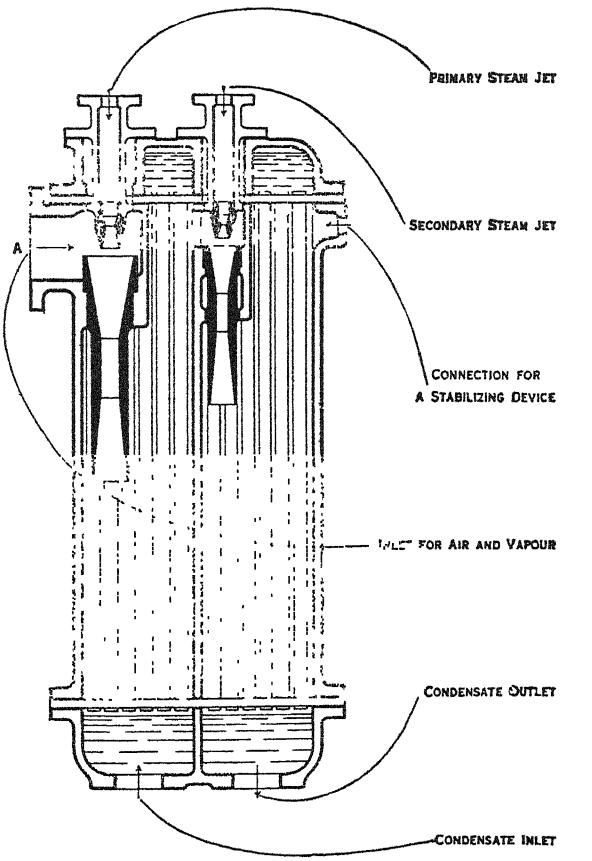
The analysis of air masses is to a large degree a matter of judgment based on a knowledge of the conservatism of the properties with time, season and region of the globe, and of the accuracy and representativity with which the properties can be measured in practice.

The occurrence of contrasting air masses with relatively sharp separations is a phenomenon mainly of the lower layers of the atmosphere, for the distinctions between the air masses readily identified near the ground are seldom traceable above 15,000 ft.

(R. G. SE.)

AIRPORT: *see* AERODROME.

**AIR PUMP.** This appliance was introduced by James Watt in 1765, when he invented the separate condenser for steam engines, in order to extract a mixture of air, water and vapour from the condenser, so providing the maximum practical vacuum. The air pump may be built as a part of the engine with its piston moved to and fro by a rocking lever, or sometimes by an extension of the engine piston rod through the back head of the cylinder A separate drive by engine or motor makes the air pump an independent unit. An arrangement of valves allows the inrush of air and vapour on the suction stroke, and expulsion through other valves on the return stroke.



BY COURTESY OF W H ALLEN SONS AND CO , LTD , BEDFORD

FIG. 1.—THE WORKING PRINCIPLES OF EDWARD'S AIR PUMP

The function of the pump is to extract the water and air from a condenser. As the piston descends at high speed the water collected below it is driven with force up the curved walls and through the ports. On the rise of the piston the air is forced out through the delivery-valve with a portion of the water

A simplified pump has a conical-shaped piston or bucket (fig 1) which dashes at high speed down on to the water collected below which it drives upward into the pump barrel above the bucket, which has just uncovered the ring of ports The water, vapour and air shoot up the barrel and out through the top valve.

Modern pumps move the air independently of the water. The ejector type of air pump is the most popular A steam jet extracts the air and vapour from the condenser, which it discharges to the second jet, which finally ejects the air against atmospheric pressure. The ejector may incorporate a small condenser, an arrangement seen in the drawing (fig. 2), consisting of a series of small tubes through which water from the condenser (termed the "condensate") is pumped. The primary steam jet sucks in air in the direction of the arrow at A, and discharges it along with the operating steam into the first condensing compartment. The secondary jet withdraws the aerated vapour from the first compartment and sends it with its operating steam into the second condensing compartment. The heat remaining in the steam after it has done its work is thus transferred to the condensate, so acting as a feed-water heater to the latter on its way to the boiler. The tire pump is a familiar example of simple reciprocating class, though strictly it should be termed an air compressor. (*See* also VACUUM-PUMP.)

BY COURTESY OF W H. ALLEN SONS AND CO , LTD , BEDFORD

FIG. 2.—DIAGRAM SHOWING OPERATION OF AN EJECTOR AIR PUMP

The type shown is operated by steam jets. The primary steam jet withdraws air and vapour from the main condenser and discharges to the secondary jet which finally ejects the aerated vapour at about atmospheric pressure. The tubes constitute a small condenser which helps to warm the condensate ready to go back into the boilers

**AIR RAIDS.** Air raids are efforts to destroy objectives on the surface of the earth by means of missiles released from aircraft in flight. They are the means of expressing the offensive in air warfare. As their name implies, they were initially looked upon as a means of harassing an enemy, and no great or decisive effect was expected from them However, as bombing aircraft became larger and more efficient, the destructive potentiality of air raids increased, until great towns were devastated, industry and transportation brought to a virtual standstill and the war-making capacity of nations fatally undermined by means of bombing from the air.

In World War I, London was the principal objective of the German air raids. On their side, the Allied air forces repeatedly attacked the industrial centres of the Rhine. The number of aircraft employed and the weight of bombs dropped in these operations were negligible by the standards of 1944–45.

In World War II, air raids worked up in a crescendo from the minor affairs of the early months of the static war (though the bomb attacks on Poland in Sept. 1939 were an indication for the future), through the relatively intense bombing of England by the Germans, to the massive Allied attacks on the axis. The end came with the V-1 and V-2 raids on England and Belgium in 1944 and 1945 and the two atomic bombs on Japan in the summer of 1945, which heralded, but were not the reason for, the Japanese surrender.

In the course of these developments, the whole technique of bombing underwent several complete transformations because of the ever increasing weight of explosive dropped from larger and larger fleets of more and more powerful aircraft, and the introduction of mechanized and radar aids to navigation, interception and bomb aiming such as had hardly been dreamed of when the war began. Finally, the perfection of the atomic bomb and its experimental use against Hiroshima and Nagasaki opened up the possibility of a new era in bombing in which not the size of the bomber fleet but the destructiveness of the individual bomb would be the determining factor in the effectiveness of the raid.

## AIR RAIDS IN WORLD WAR I

From a historical, though no longer from a military point of view, the raids on Great Britain, France and Germany in World

War I are worthy of study. In the exercise of its characteristic ability to overpass the enemy's armed forces and attack the heart of the country and its war industries, the air arm had shown that an end once and for all had been put to the possibility of limited conflicts. Henceforward, war meant total war.

**Raids in 1914–15.**—In Dec. 1914 a couple of bombs were dropped in the sea off Dover, and three days later, on Dec 24, the first German air projectile hit English soil. A few half-hearted attacks by aeroplanes during 1915 were ineffective, and it was left to the lighter-than-air machines to cause the first damage. On Jan. 19, 1915, naval Zeppelins dropped bombs on Yarmouth and Cromer and killed four people The first raid on London occurred on the night of May 31, 1915, when a single military airship caused 41 fires and 5 deaths. On June 6, Hull was bombed, with 24 fatal casualties and the destruction of 40 houses. On this night an airship, the LZ37, was destroyed near Ghent on its homeward journey by Lieut. R. A J Warneford, R.N., who received the Victoria cross for his exploit.

During the latter months of 1915, London was bombed four times. Damage amounting to £500,000 was caused, and in a raid on Woolwich 33 people were killed and 77 wounded.

**Raids in 1916.**—In the early part of the year, the British defenses had little success against the Zeppelins. On Jan 31, 1916, nine Zeppelins had their own way over the midland counties, and bombs dropped on Shrewsbury killed 59 people Of 16 British aircraft which took off to intercept, 8 crashed on landing. By the spring, however, the British defense measures improved. The L15, one of the five Zeppelins that attacked on March 31, was hit by gunfire, attacked in the air by Lieut. A. de B. Brandon of the royal flying corps and crashed into the sea off the coast of Essex. However, 15 raids on England and Scotland during April caused 84 deaths.

On Sept 2 London suffered a raid by 14 Zeppelins, of which one, the SL11, was destroyed in flames near Cuffley, Middlesex.

On Sept. 23, 1916, three of the newest super-Zeppelins attacked London. Of these, the L33 dropped 20 bombs, but the city was no longer helpless. Lit by searchlights, the airship was riddled by fire from guns and aircraft and landed near Colchester, its crew being made prisoners. A second aircraft, the L32, was brought down in flames at Billericay. Meanwhile, the third ship, piloted by Mathy, the boldest of the Zeppelin commanders, reached London and dropped a number of bombs on the outskirts and returned safely to Germany. The British casualties on this night were 40 killed.

Mathy's career was brought to an end on Oct. 1. Eleven Zeppelins crossed the coast at Lowestoft and steered toward London. Under heavy gunfire, Mathy in the L31 was brought down in flames at Potters Bar. During the whole raid by 11 aircraft, the British loss was only one killed. The defense of London had now definitely mastered the lighter-than-air attacks, and no German airship thereafter flew intentionally over the metropolis.

The first attack with airships on England in 1916 was made on [illegible] when eight Zeppelins reached the coast, one being brought down over Hartlepool and another at Yarmouth, after a remarkable flight across England to Cheshire and back to the east coast. Before the end of the year, the first aeroplane attack on London was made by a single aircraft which dropped six small bombs in daylight with slight result.

**Raids in 1917.**—By the end of 1916, the German command had come to the conclusion that it must try new methods. Early in 1917, therefore, they began to equip a squadron of aeroplanes for the systematic bombing of England.

The squadron began to operate about the end of May, but its first two attempts to reach London were unsuccessful, though in one of them a Canadian camp at Shorncliffe and a street in Folkestone were bombed causing 133 fatal casualties. One of the aircraft was hit by anti-aircraft fire and fell into the Thames. The third attempt on London was more successful. A bomber squadron attacked the city just before noon on June 13, 1917; 72 bombs were dropped in the neighbourhood of Liverpool street station, and casualties were caused amounting to 104 killed and 423 injured.

London was again successfully raided by 22 aircraft on July 7. Seventy-six bombs destroyed a number of buildings, damaged the general post office, killed 46 people and injured 123. The anti-aircraft fire was unsuccessful in hitting any of the raiders. The failure of the defense measures caused a public outcry, and the government ordered a complete reorganization The London air defenses were formed into a separate command and, under Gen. E. B. Ashmore, included all means of defense, both ground and air.

The new arrangements were soon tested. On Aug. 12, nine Gothas, heavy bombing machines, made landfall at Harwich and turned inland for London. The communication system of the defense control worked well, and the squadrons immediately defending London were at the required height in time to meet the enemy formation. The attack was beaten off, and the bombs were unloaded at Southend, where 32 people were killed.

An abortive attack by eight Zeppelins was made on the midlands on Aug. 21, and the next day the last daylight attack was made on England, when 13 Gothas started out to bomb Sheerness and Dover. British seaplanes turned them back from their objective, and three of them were destroyed by gunfire.

**Night Attacks Begin.**—The first group of night attacks by aeroplanes came in the beginning of September. On the night of Sept 3–4 hostile aircraft came in over the North Foreland and, though they did not reach London, one of them dropped a bomb on a building at Chatham where a number of naval ratings were asleep, killing 107 and wounding 86. The following night, the German squadron reached London, though a number of the aircraft were turned back by gunfire. This time damage caused was small and the total casualties amounted to only 14 killed and 48 injured.

The defenses had profited from their experience of these early night raids, the pilots in the handling of their aircraft at night and in finding their objectives, and the anti-aircraft guns in the evolution of a barrage system of fire which disconcerted the raiders.

On the night of Sept. 24, the Germans launched a double raid with an aeroplane attack on London and a simultaneous Zeppelin raid on Hull. In London, barrage fire turned back most of the raiders and brought 1 down, but 27 British aircraft which took the air failed to find the enemy. The airship raid on Hull had slight success.

During this period, barrage fire scored a considerable success in turning a large proportion of the attackers back before they had reached their target, but it was expensive in ammunition; and the defending squadrons of aircraft were still far from an efficient instrument because the central control could give no information to pilots once they had left the ground.

An airship raid on the night of Oct. 19–20 had points of special interest. Eleven airships met off the Yorkshire coast to attack industrial centres in the midlands. They flew at more than 16,000 ft., where they suffered greatly from cold and also encountered a strong northerly gale before which they drifted south helplessly. One airship crossed London and dropped a bomb on Piccadilly circus, though without realizing its whereabouts. The raid ended in disaster for the attackers. One flew back to Germany in the normal way, six got back by flying over the Netherlands or across the Allied lines, but the remaining four were destroyed on French territory.

At the end of October, the Gothas renewed their raids on London, but the defenses of the capital were showing steady improvement. Two Gothas were brought down by anti-aircraft fire on Dec. 6. In a raid on Dec. 18, the Germans first used a giant aircraft which dropped a 300 kg. bomb near Eaton square, making a large hole but doing little damage.

**Raids of 1918.**—During the first quarter of the year, five aeroplane raids took place, the Germans showing a tendency to employ more and more of the giants in place of the smaller Gothas. One Gotha was destroyed by a fighter on Jan. 28, on which night a bomb dropped by a giant aeroplane fell on a building which was being used as an air-raid shelter, and 41 people were killed. The use of the 300 kg. bomb was now becoming

general, and the damage caused by it was considerable. On March 7, the only aeroplane raid on London in a nonmoon period took place.

Meanwhile the Zeppelins began their last series of raids on England on the night of March 12. They now tended to bomb from a considerable altitude, and the damage caused was generally slight. Their last appearance was on the night of Aug 5–6, when five Zeppelins came up the coast of Norfolk. No bombs were dropped on land and the L70, the latest word in airship construction, was destroyed

In the great aircraft raid of May 19, 1918, the Germans made their maximum and final effort of the war with this form of attack. Between 30 and 40 Gothas and at least 2 giants took part. Thirteen raiders managed to reach London, and the damage was considerable; 34 people were killed and 98 injured. By this time, however, the defense was really something to reckon with The Germans lost seven aircraft: three were shot down in air combat; three were destroyed by gunfire; and one was compelled to make a forced landing because of engine failure. This defensive success was final, and the German air force made no further attempt to bomb London.

In the raids during World War I on England, the Germans employed 435 aircraft and 208 airships, which dropped 2,869 and 5,907 bombs respectively. In these raids 1,316 people were killed and 3,000 injured, and the material damage caused was considerable. Over and above this, the holdup of work in factories because of the presence of enemy raiders and the slowness of the personnel in returning to work in vulnerable areas after a raid had taken place had a far from negligible effect on production.

## AIR RAIDS IN WORLD WAR II

The possibility of raids of overwhelming severity had been impressed upon the people of Europe with great clarity during the period before the outbreak of war in 1939. The raids that had been carried out by the Italians in Ethiopia, admittedly against a primitive people entirely unprovided with defense against air attack, and the air attacks by both sides on troops and centres of population during the Spanish Civil War had made the world very bomb conscious. Moreover, most of the European countries had given much attention to measures of civil defense, in the course of which the dangers of neglect to comply with the precautions recommended had been painted in the most sombre colours. The likelihood of bombardment with poison gas had been stressed, and it was widely expected that this form of attack would be employed by a ruthless enemy from the first, as it had in fact been used by the Italian air force in Ethiopia, though not by either side in Spain.

Though most of the ideas held by the general public about air bombardment were in the highest degree fanciful and were later falsified by events, World War II began with an exhibition of air bombing which showed how important a part this form of offensive would play in modern war.

**The Continental Campaign, 1939–40.**—On the morning of Sept. 1, 1939, when the German campaign against Poland was launched, the German air force struck heavily against the Polish air force. In less than three days the air raids directed against its aerodromes caused the complete destruction of Polish air power as an effective means of resistance. Then the attacks were switched on to railway bridges, locomotives and rolling stock, to break up the lines of communication of the Polish armies. As resistance crumbled, the air raids were directed against columns of moving men and vehicles on the roads and, finally, they were centred on Warsaw, the last seat of resistance. The city suffered heavy damage.

On the western front, the first eight months of the war saw few large-scale air raids by either side. Extensive reconnaissance flights were made and data collected for the real struggle to come. In the spring of 1940 it came with great violence.

In the attack on France and the Low Countries, the German air raids were designed to assist their ground forces. In the Netherlands, parachute troops and air-borne infantry were used with striking success. Just as the Netherlands capitulated, a three-hour air raid was directed against Rotterdam. A high degree of damage resulted, and the heart of the city was wrecked

In France and Flanders, air attacks were made upon key for tresses in the great systems of French and Belgian ground defenses as well as against the French air force and railway system. The concentration of air power was so intense that the German ground forces had little difficulty in breaking through.

Under the shield of air attack the German army drove relentlessly forward to trap the British expeditionary force at Dunkirk. There the royal air force established a local fighter defense that largely nullified the strength of the German air attack, and the Germans were unable to destroy the forces being evacuated across the channel.

**The Battle of Britain.**—After the fall of France there was a comparative lull in air activity for about six weeks. Then, in August, the Germans launched a heavy air offensive against England as a preliminary to their projected invasion Though the possibility of invading the British Isles rapidly faded in face of the defensive strength of the British air forces, the bombing offensive, mainly directed against London, was sustained for many months.

Initially, the German air staff concentrated its efforts upon the elimination of the British fighter force by attacks upon aerodromes, aircraft factories and radio-location (radar) stations, while at the same time attempting to lure the fighters into the air by attacks upon shipping. Although it inflicted much damage in these attacks, the *Luftwaffe* lost heavily (76 aircraft on Aug 15), and by the end of August the first phase of the battle of Britain was over, leaving the German air staff with many lessons to digest.

During the second phase, the attacks were concentrated mainly

TABLE I—*Air Raids on Great Britain in World War II*

| Cities and towns most heavily raided | | | |
|---|---|---|---|
| Place | Tonnage of aircraft bombs dropped (metric tons) | Casualties | |
| | | Killed | Seriously injured |
| London | 12,238 05 | 29,890 | 50,507 |
| Bristol | 988 91 | 1,223 | 1,149 |
| Liverpool (and Birkenhead) | 882 88 | 3,219 | 3,073 |
| Coventry | 854 62 | 1,250 | 1,858 |
| Birmingham | 823 84 | 2,337 | 2,924 |
| Hull | 744 80 | 1,212 | 1,051 |
| Manchester | 496.42 | 577 | 583 |
| [illegible] | 489 56 | 1,169 | 1,102 |
| [illegible] | 452 47 | 598 | 889 |
| [illegible] | 342 48 | 624 | 568 |
| Glasgow | 311 72 | 776 | 597 |
| Portsmouth | 259 69 | 847 | 1,113 |
| Swansea | 243 87 | 380 | 401 |
| Belfast | 182 29 | 967 | 678 |
| Canterbury | 179 00 | 114 | 127 |
| Norwich | 154 31 | 326 | 362 |
| Bath | 132 07 | 415 | 371 |
| Cardiff | 118 08 | 263 | 353 |
| Folkestone | 103 60 | 123 | 124 |
| Exeter | 95 92 | 272 | 241 |
| Dover | 81 91 | 232 | 371 |
| York | 59 53 | 85 | 118 |
| Total for the whole of Great Britain | 70,995 00 | 60,595 | 86,182 |
| [illegible] | | | |
| [illegible] ise of Great Britain | | | 3,747½* |
| [illegible] | | | 833 |
| [illegible] | | | 24 |
| Pilotless aircraft or flying bombs (V-1) | | | |
| Target Principally London area and Manchester | | | |
| Estimated number launched (from ground) | | | 9,239 |
| (from air) | | | 1,287 |
| Number that fell in target area | | | 2,420 |
| [illegible] down by guns | | | 1,878½* |
| [illegible] down by fighter aircraft | | | 1,846½* |
| [illegible] down by balloons | | | 231½* |
| Total brought down by all arms | | | 3,957 |
| Casualties | | | |
| Killed | | | 6,184 |
| Severely injured | | | 17,981 |
| Slightly injured | | | 24,493 |
| Rockets (V-2) | | | |
| Target Principally London area and Norwich | | | |
| [illegible] launched | | | not known |
| Number reported by the defenses | | | 1,115 |
| Number that fell in London area | | | 518 |
| Casualties | | | |
| Killed | | | 2,754 |
| Severely injured | | | 6,523 |
| Slightly injured | | | 15,438 |

*Fractions relate to claims shared between different arms of the defense
Source Compiled from data given by the Home Office and by the Air Ministry, London.

upon London and were made both by day and by night. With the exception of the attack of Sept. 7, 1940, with about 400 aircraft, the *Luftwaffe* was unable to break through to the heart of London by day, and though the casualties and damage inflicted on that occasion were heavy, its own casualties during these weeks, which reached a figure of more than 50 on some days, convinced it that daylight raids in face of the defenses of the metropolis did not pay. A week later, in the course of raids on the outskirts of London and the south coast, the German air force suffered heavily, losing 56 aircraft in one day.

In the final, long drawn out phase of the battle, heavy and sustained night attacks were made against London and other British cities, but there was little real military purpose behind them. Almost nightly for three months, up to the end of 1940, German bomber attacks averaged 200 sorties a night The casualties they inflicted during this period were heavy, but they failed to break the spirit of the people or vitally to damage industry. The general accuracy of the bombing was poor, with a high proportion of bombs falling in open country or on unremunerative targets Later, although attacks continued to be made for a time and damage resulted to London and a number of other towns of industrial or cultural importance, the German bombing policy lost its objectivity, and with the *Luftwaffe's* preoccupation elsewhere and the greater strength of the British defenses, heavy aircraft raiding of England virtually came to an end by the early summer of 1941.

**Malta and the Mediterranean.**—The Germans next switched their attention to the Mediterranean, where their Italian allies were in need of support in their African campaign. It was first necessary to eliminate Malta as a platform for British aircraft capable of harassing the sea routes; and therefore 1941 and early 1942 saw a heavy air offensive carried out against the island. The German bomber force consisted of about 150 Junkers 87s and 88s, protected by Italian fighters, and Malta, with the slenderest of fighter defenses, suffered heavily, not only from attacks on the island itself, but through the losses incurred by convoys attempting to bring in fuel, food and reinforcements. The bomb attacks on Malta, however, always just failed to be sufficiently sustained to achieve their object, and the need to divide the *Luftwaffe* to deal with the needs of the desert campaign in Africa and of the successive attacks upon the Balkan countries and Russia meant that the bomber forces were too weak to deal a knockout blow anywhere. During 18 months fighting in the Mediterranean, the Germans were generally trying to do too many things at the same time, with the result that they were weak and comparatively ineffective everywhere. By June 1942 their Mediterranean air offensive was over, and thereafter the initiative swung to the side of the Allies. British bombers cooperated with ground forces in beating Field Marshal Erwin Rommel's armies in Africa; they helped the Allied forces to sweep forward to Italy; captured aerodromes gave the bombers [illegible] operate over the Alps into southern Germany; and the main Allied bombing policy now began to exhibit the rudiments of the plan that led on to an unbroken succession of attacks of increasing intensity and the staggering blows that were to paralyze German and Japanese resistance three years later.

**The *Luftwaffe* in the Russian Campaign.**—In the U.S.S.R., the *Luftwaffe* commanders proved that they had really learned [illegible] experience which they had by now received in the handling of air forces in modern war. For them, air power was [illegible] to be used for the tactical benefit of the armies in the prosecution of the blitzkrieg, the one form of warfare upon which the German high command relied for the achievement of victory For this reason, there is little to be learned by the student of war from a consideration of the bomber operations which took place on either side during the Russian campaign. The heavy bomber raids on Moscow and other soviet cities were for the most part badly planned affairs in which heavy losses were [illegible] fighters and anti-aircraft defenses, whereas relatively [illegible] damage was done to the objectives. On the soviet side, bombing took rather a haphazard form and had little effect upon the progress of operations.

**The Strategic Plan.**—Despite the failure of the Germans to achieve their objective in the battle of Britain, there were those on the Allied side who were unshaken in their belief that a bomber offensive properly directed, unfalteringly sustained and of sufficient weight would prove decisive in the winning of the war. The errors made by Germany in directing air offensives against the British Isles, in the Mediterranean and in the course of the Russian campaign were evident, and by 1942 the inability of the *Luftwaffe* to play a decisive role was obvious. Since the beginning of the Russian campaign, the *Luftwaffe* had been fighting on three fronts at once, and already the German aircraft industry was swinging away from the construction of strategic bombers to concentrate on tactically offensive or purely defensive types. The British royal air force early initiated a policy of night attack upon German industry and had continued these attacks to the limit of its strength in unbroken and increasing intensity.

Soon after the entry of the U.S. into the war, U.S. bombers began to arrive in Great Britain to take their part in this offensive. Within six months more than 400 heavy bombers were based on British aerodromes, and on Aug. 17, 1942, 12 Flying Fortresses made a day attack on the railway marshalling yards at Rouen, France, and returned without loss. The day and night partnership of the U S. and British bomber forces had begun.

In Jan. 1943 the Allied leaders at Casablanca authorized an increased bomber offensive and defined its object as "the destruction and dislocation of the German military, industrial and economic system and the undermining of the morale of the German people to the point where their capactiy for armed resistance is fatally weakened." It was clear that the ability of the bomber forces to implement this directive largely depended on the possibility of checking the activities of the German defensive fighter forces. A first call upon the activities of the bombers was, therefore, to destroy the factories where the fighter aircraft were constructed, together with the engine, ball-bearing and accessory plants associated with them Once a sufficient degree of immunity from interference had been won for the bombers, they could turn their destructive activities to other and more direct sources of the enemy's power of resistance.

The new offensive began forthwith and, despite heavy losses to both the Allied air forces, considerable results were achieved: the rate of delivery of fighter aircraft to German air force units was sensibly reduced. Though the effect of this slowing up of production was not felt immediately, the shortages that were ultimately imposed on the fighter units had a significant effect upon their ability to interfere with the Allied attack at a most critical stage of the war early in 1944.

Although right up to the end of World War II Germany continued to concentrate the main portion of its aircraft productive capacity on the output of fighter aircraft to defend its cities and industries against the increasing weight of bomber attack and though the Allied bombers continued to suffer severely from German fighter attack, sufficient freedom of action was won for them to attack with increasing force every phase of German life and war-waging activity and especially its cities, transportation systems, fuel and heavy industries. The Allied air staffs devoted much energy and ingenuity to the collection and interpretation of information concerning German industry and in assessing its vulnerability to raids and the speed at which it would recover from such attacks. As time went on, valuable information was accumulated and many earlier estimates of the effect of bombing upon industrial targets had to be reconsidered. For instance, intelligence sources indicated, and postwar investigation afterward confirmed, that even the most destructive raids often had a much smaller effect than was expected upon the productive potential of a plant. Generally speaking, it may be said that the most rewarding strategic targets were oil and nitrogen plants and attacks upon transportation targets. Later, when the royal air force turned to area bombing of towns, one of the most important effects upon the enemy war-making capacity was the number of workers who had to be diverted from productive work to such activities as debris clearance, reconstruction and the

replacement of household goods destroyed in raids. It was estimated that by the end of 1944, 20% of the German labour force, excluding agricultural workers, was engaged in this type of work.

**Invasion of the European Citadel.**—In the preparation for the invasion of the German fortress of Europe, the air had a many-sided offensive role to play. In the long period of preparation, when attacks upon the centres of production and the means of transportation were most important in order to prevent the enemy from reinforcing and supplying his defensive forces, the ability of the bombing forces to make deep penetrations into Germany depended largely upon their freedom from interference. During the early part of 1944, therefore, the long-range fighters which could accompany the bombers to their objectives—notably the U S. P-51 Mustang fighter—had a vitally important part to play. By tempting the German fighters, whose production was already suffering from the offensive against the aircraft factories, into the air and destroying them there, the Mustangs not only enabled their bombers to attack their objectives with success but also ensured that, when the invasion came, the ground forces could proceed from the United Kingdom virtually immune from attack from the German air force.

In the invasion itself, the air forces played manifold roles in conjunction with the surface forces. Saturation bombing (as at St Lô, where 2,500 bombers operated against an area 3,000 yd. by 7,000 yd. for two-and-one-half hours on end) was used to facilitate local attacks. Raids upon bridges, railway and road junctions, supply dumps and communications centres were practically continuous as called for by the land commanders to soften enemy resistance and enable the program of advance to be maintained: and, as a background to all these tactical interventions, the steady bombing of fuel and manufacturing targets went on in order to starve the enemy of the means to move and fight. Against these activities the enemy air forces were able to do little, since the great preinvasion offensives had had the effect of draining them of their lifeblood.

**The Pilotless Aircraft and Rocket Campaign.**—For more than a year before and during much of the invasion period, a considerable proportion of the Allied bomber force had had to be diverted from an offensive to what was, in reality, a defensive role. The preparations which the Germans were making to open a heavy attack with pilotless aircraft and rockets against England became known to the Allies in 1943, and from then on heavy and frequent attacks were made upon the factories where these weapons were being produced and upon the hydrogen and liquid oxygen plants that produced their characteristic fuels. Moreover, as soon as the construction of launching sites on the northern coasts of the continent opposite southern England was observed, these sites were subjected to a high intensity of attack. The beginning of the actual attack by the V-1 pilotless aircraft on England was practically simultaneous with that of the invasion of Normandy, and it is clear that, had the launching sites and manufacturing centres not been attacked as they were, the V-1 offensive would have begun earlier and in greater intensity and might have seriously interfered with the invasion preparations. As it was, more than 8,000 V-1's were launched against England and nearly 8,000 against continental targets, chiefly Antwerp, after the Allied forces were in occupation of the continental channel coast. The rocket attacks came mainly from the Netherlands and western Germany; a total of 1,100 exploded in England and 1,675 on the continent, again chiefly on Antwerp, which was in use as an Allied invasion port. London was the usual objective of the attacks upon England, though inevitably the southern counties on the route of the V-1s and V-2s to London were sprinkled with those that fell short or were intercepted and shot down on the way. In the course of countermeasures against these missiles, a campaign which lasted for 13 months in all, a total of 100,000 tons of bombs was dropped, representing 9% of the total tonnage dropped by the Allied air forces from the United Kingdom during the period. Quite apart from the damage actually caused by the weapons themselves, the threat which they represented had thus a considerable value for the Germans in diverting Allied bomb tonnage away from industrial targets and centres of population.

**Statistics of Air Raids in the European Theatre.**—During the course of the war in Europe, the Allied air forces flew nearly 1,500,000 bomber sorties from the United Kingdom against the axis. In these, nearly 2,750,000 tons of bombs were dropped, with a loss of more than 20,000 bomber aircraft and nearly 160,000 men, divided almost equally between the U.S. and British air forces.

TABLE II—*Allied Bomb Tonnage Dropped at Principal European Target Systems of the Axis Powers, 1939-45*

| Type of target | Tonnage dropped (to nearest 1,000 tons) | Percentage of total |
|---|---|---|
| Aircraft factories | 48,000 | 1.8 |
| Miscellaneous manufactures | 70,000 | 2.6 |
| Water transport | 113,000 | 4.2 |
| [illegible] | 54,000 | 2.0 |
| [illegible] | 186,000 | 6.9 |
| Oil, chemicals, rubber | 251,000 | 9.3 |
| Military targets | 300,000 | 11.1 |
| Industrial areas | 640,000 | 23.7 |
| Land transports | 867,000 | 32.1 |
| All other targets | 170,000 | 6.3 |

Table II gives the distribution by percentages of the bomb tonnage dropped on Germany and countries in association with or occupied by it; while German statistics show that, as an incidental concomitant to the Allied raids, more than 3,500,000 dwelling houses or flats, about 20% of the total, in Germany were destroyed or heavily damaged; 250,000 civilians were killed and more than 300,000 seriously wounded. A comparison of these figures with those for casualties in the raids on England in World War I offers a grim commentary on the progress of air bombing between 1914 and 1945.

**The Pacific Area.**—On Dec. 7, 1941, Japan opened its campaign against the U.S. in the Pacific with a temporarily overwhelming display of air power, employed without warning at a time of international tension but when the two countries were still officially at peace. For negligible losses, the Japanese air force at Pearl Harbor practically eliminated U.S. naval power in the Pacific for the time being. On Dec. 10 the sinking of two major British naval units off Malaya for the loss of only four medium bombers lent further point to the lesson that naval forces were an easy prey to air attack unless provided with air cover. Within a few months, under an air umbrella and helped forward by air bombing against weak ground forces, the Japanese had overrun Malaya, the Philippines and Burma, as well as having gained control of vast areas of the Pacific, all at very minor expense in men and equipment.

On the Allied side, the really significant air event of this period was an air raid led by Gen. James Doolittle on Tokyo on April 18, 1942. Though the material damage caused was slight, the proof of vulnerability to attack in the heart of its empire which this raid gave to the governing junto in Tokyo persuaded it to expand its perimeter beyond the limits which it could possibly defend and supply and thus sowed the seeds of its ultimate collapse. Thus, though Gen. Doolittle's exploit was looked upon at the time rather as a superb gesture of defiance than as a serious contribution to the winning of the war, a retrospective view puts it into a very different perspective.

For the next two years, the main air problem for both sides was to bring aircraft within range of the enemy. Over the great distances of the Pacific, it was possible often to strike at the enemy only with carrier-based forces. The target was sometimes the enemy fleet, sometimes the garrisons and installations on islands on the perimeter of the Japanese sphere of domination. At all times, Japanese merchant shipping, vital to the supply of their armies, received a full measure of attention from the U.S. bombers. Within a year of Pearl Harbor, 4% of the whole of the Japanese merchant fleet had been sunk by aircraft action alone, and it continued to be a high priority target until the end, by which time, of a total of 9,000,000 tons sunk, nearly 3,000,000 tons had been destroyed by air attack. At the same time, concentrated bombing of the Japanese navy took a heavy toll. Of a total of 2,250,000 tons of warships possessed by Japan, nearly 700,000 tons were sunk by air attack in the course of World War II.

In areas where it was possible for air forces to operate from land bases against Japanese-held outposts, it was necessary to provide such bases at short notice and to strike from the air against the long lines of communication, whether by sea to the Pacific islands or by land as in Indo-China and Burma. While, on the ground, the Japanese were largely on the defensive, their air forces often struck back hard and it was not until early 1943 that the initiative in the Pacific had definitely passed to the Allies.

But, just as in Europe the main objective of the air raids of both sides was the heart of the enemy's home territory, so in the Pacific war, the U S looked to the attack on Japan's industry and home population as an essential feature of its defeat. The U.S. was fortunate in that at no period of the war was it in serious danger of air raiding of its home country by the Japanese bomber force, except for the possibility of tip-and-run raids from carrier-based forces against the Pacific coast, which in fact never took place. The nearest the enemy got to bomb attacks on the United States homeland was the random release of some explosive-loaded balloons, designed to fall in the western states The nuisance value of this primitive form of attack was, however, slight.

To attack the Japanese home islands, air bases had to be secured within 1,500 mi. of them to enable the long-range bombers to operate This dictated a large-scale advance from the perimeter, on the south to the Philippines; in the central Pacific to the Marianas and on to Okinawa. In the course of these preparatory operations, air power was exploited to the utmost, air forces being used from carriers and from specially constructed air bases within range to smother enemy resistance and neutralize air forces. To hold this air offensive in check, the Japanese committed all their available aircraft and suffered losses which they were never afterward able to make good, although production of aircraft had increased greatly, reaching more than 2,000 a month in 1944. In spite of losses in aeroplanes amounting to 9,000 in the Philippines campaign, the output from Japanese factories should have been sufficient to maintain first-line strength had air crew training and ground services matched production; but in these particulars, the Japanese air staff failed seriously, and the air force fell lower and lower in the scale of efficiency.

**Suicide Bombers.**—It was the recognition of their inability to equal the Allied air forces in efficiency that led the Japanese commanders to exploit the willingness of their pilots to engage in suicide attacks, the so-called Kamikaze technique in which the pilot deliberately crashed his explosive-laden aircraft into his objective In all the Japanese flew 2,500 suicide sorties, of which 475 secured hits, sinking 45 ships and doing serious damage, [illegible] battleships and 16 aircraft carriers. In [illegible] direct effect the U.S. air force was constrained to divert 2,000 heavy bomber sorties from industrial targets to Kamikaze bases.

**Attacks upon the Japanese Homeland.**—A chain of islands with relatively small quantities of basic raw materials available [illegible] the Japanese empire was ill equipped to fight a major [illegible] power in the absence of adequate supplies from overseas. [illegible] the Asiatic mainland in the years before [illegible] Japan remained almost completely dependent upon its sea communications for its war-making capacity By the virtual destruction of its merchant fleet, it was reduced to such a condition by 1944 that its ultimate defeat by exhaustion of supplies was inevitable. Nevertheless, the Allied strategy contemplated an invasion of Japan, for which a bombing offensive against its industries and cities was a normal preliminary

The offensive opened from the Marianas in Nov. 1944. At first the targets selected were mainly air frame and aero-engine factories; but in March 1945 a decision was taken to act directly against Japanese centres of population, with the object of destroying the will to continue the struggle.

[illegible] period of ten days, more than 9,000 tons of bombs were dropped, causing the total destruction of 31 sq mi. in the four towns of Tokyo, Nagoya, Osaka and Kobe. Thereafter, bombing attacks alternated against towns, factories, oil refineries and airfields. In all, 160,000 tons of bombs were dropped against Japan itself, as against nearly 1,500,000 tons dropped on Germany. Nevertheless, the physical destruction in Germany and Japan resulting from air raids was comparable. The attack on Japan was more concentrated in time, and the target areas were more vulnerable. Forty-four per cent of the built-up area of 66 cities was destroyed and 30% of the urban population of the whole country lost their homes After five months of bombing, the Japanese economy was very close to the breaking point, even without other factors.

**The Atomic Bombs.**—Early in Aug. 1945, the first two atomic bombs ever used in war were dropped by a U S aircraft on Hiroshima and Nagasaki respectively. In the two attacks, 100,000 people were killed and six square miles of built-up area completely devastated. It was calculated that the damage caused by these two bombs was equal to that which would have been done by 345 B-29 bombers carrying more than 3,000 tons of conventional bombs.

Though, indeed, the Japanese government had been casting about since early May to find a way to end the war, the effect caused by the explosion of the two atomic bombs and the fear of similar attacks was used by them as a reason for an immediate surrender.

**Conclusion.**—In the course of two world-wide conflicts within the space of 40 yr., the technique and potentiality of raiding from the air had progressed from the dropping of a 20 lb. bomb from a single aircraft to the unloading of millions of tons of explosive and two atomic bombs by many thousands of aircraft. The effect of air bombing had, in the same period, passed from being a mere irritant to playing a main role in deciding the issue of wars.

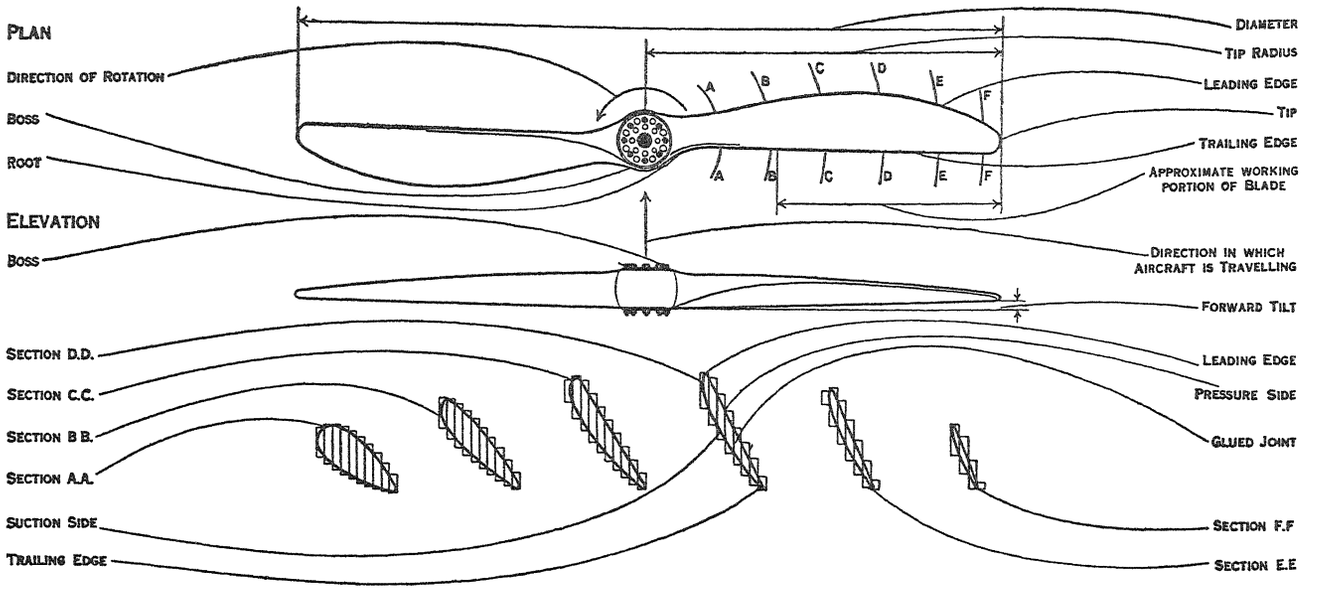
(D. CR.)

**AIRSCREW**, the designation of all those devices which, when rotated, [illegible] screw their way forward, sucking the air from in front and throwing it away behind, or which, when placed in a moving stream of air, are themselves rotated. The term covers: (1) fans of a certain type; (2) screw propellers working in air; (3) helicopters; (4) windmills; (5) gyroplanes.



(1) If the airscrew is rotated but restrained from forward movement, air is drawn in from the front and thrown back behind, and the airscrew acts purely as a fan.

(2) If the airscrew is not so restrained, the thrust caused by moving the air backward drives forward the airscrew and the aircraft, or body, to which it is attached. The airscrew is then acting as a propeller. The thrust exerted, and the volume of air moved, have their maximum value when the airscrew is acting purely as a fan. As the airscrew moves forward, the volume of air delivered and the thrust exerted decrease, and at a certain speed become nothing At this forward speed the distance moved in one complete revolution is known as the experimental pitch of the airscrew. The thrust acts approximately in a horizontal direction.

(3) If, however, the airscrew is placed so that it exerts its thrust upward in an approximately vertical direction, it is then acting as a helicopter.

(4) In the above conditions the airscrew is driven by some engine or motor, but if it is placed freely on a shaft in a wind, or if it is moved forward through the air, it will rotate and some of the energy in the moving air will be transformed into useful work and transmitted to whatever mechanism is attached to the airscrew. The airscrew is then acting as a windmill. The wind blows approximately in the direction of the airscrew shaft; *i.e.*, at right angles to the plane of rotation.

(5) If the wind blows at a small angle to the plane of rotation, the airscrew will not only be caused to rotate, but in doing so will exert a thrust. It is then acting as a gyroplane. The best known

FIG. 1.—PLAN, ELEVATION AND CROSS SECTIONS OF A TWO-BLADED PROPELLER. THE CROSS SECTIONS IN LOWER HALF OF ILLUSTRATION WERE MADE AT THE POINTS A, B, C, D, E, F, ON THE TOP FIGURE, THEY SHOW THE TWISTED SHAPE OF THE AIRSCREW BLADE

example of this use of the airscrew is the autogiro, invented in Spain by Don Juan de la Cierva. In this case the plane of rotation is approximately horizontal and the thrust approximately vertical.

**General Description.**—An airscrew consists of a boss or hub with spokes radiating therefrom—like a wheel without a rim. The number of spokes or blades, as they are technically termed, is usually two or three, though four are sometimes used, particularly on the larger British transport craft. They have seen little use in the United States, however.

In fig. 1 is shown the plan and elevation of a two-bladed airscrew intended for use as an aircraft propeller. Below them are shown the sections which would appear if the blade were cut through at points A, B, C, etc. The terms used in connection with airscrews are also shown. Note the term "diameter," the distance from the tip of one to the tip of the opposite blade. For aircraft propellers the diameter varies from as little as 4 ft. to as much as 19 ft. Note also the characteristic shape of the cross sections of the blade. Sections of this shape are called aerofoil sections; their properties will be found described in any standard work on aerodynamics. The shape of these cross sections has an important influence on the efficiency of the airscrew. It will be noticed that the blades are twisted; the angle is greater at the root than at the tip. This twist is necessitated by the fact that in order to work most efficiently, an aerofoil section must move at a small angle to the relative air flow.

Now any point in the blade has two simple motions: (1) in the direction of rotation; (2) the forward motion at right angles to (1) In fig. 2 these two simple motions are illustrated to scale as AB and AC for a point near the tip of the blade, and in fig. 3 for a point near the root of the blade; AD is the resultant direction and speed of movement. The speed AC of the forward movement is the same for both points, but the speed AB in the direction of rotation is proportional to the distance of the point from the centre. Its value is zero at the centre and a maximum at the tip.

Thus as will be seen from figs. 2 and 3, the resultant direction of movement of the point near the tip is at a smaller angle to the plane of rotation than that of the point near the centre. Since the aerofoil section must be placed at a small angle to its direction of movement, the blade has a smaller angle at the tip than near the centre. The distance travelled in one complete revolution, when the direction of the resultant motion is along the line joining the leading and trailing edge of the section (*see* fig. 1, section D.D.), is the geometrical pitch. It has approximately the same value for all parts of the blade and is usually referred to by the word "pitch."

**Problems of Design.**—The main difference between various airscrews is in the diameter and pitch, and it is the designer's object to choose these for the attainment of certain specified results. He has three aims: (1) To ensure that the airscrew runs at a certain rate of rotation when driven by a certain power, when the aircraft to which it is attached is travelling at a certain speed at a certain height above sea level. (2) To ensure that under these conditions the airscrew will give its maximum efficiency (The efficiency is the ratio of the useful work done by the airscrew to the work done by the engine in turning it. Efficiencies of from 75 to 87% are commonly attained.). (3) To ensure that the airscrew is reliable and safe Airscrews rotate at a high speed. Their tips travel at speeds varying from 700 to as much as 1,100 ft per second—a velocity exceeding that of sound. This sets up a centrifugal pull in the blade of as much as from 10 to 25 tons, in addition to which the blade must withstand the bending caused by its own thrust.

To satisfy these various requirements, the designer will specify an airscrew of a certain diameter and pitch, with blades of a certain width and thickness. If any one of these conditions alters—the rate of rotation, the power or the aircraft speed—a different airscrew will be required. Hence the infinite number of designs involved.

**Controllable Pitch Airscrews.**—From the very start of aircraft development it has been plain to engineers and inventors that it would be very desirable to alter the pitch angles of the propeller blades during flight. If the blades are set at the proper angle for level flight at relatively high forward speed, the angles are too high at the time of take-off and climb when the forward speed of the aeroplane is low, so that the propeller is operating inefficiently under these conditions. When the internal-combustion engine was adopted universally as an aircraft power plant, there was an additional need for a variable or controllable pitch airscrew, since a propeller which was set for the proper engine rotation at level flight would not allow the engine to turn at its full rated speed at the time of take-off, so that there was a material loss in engine power under these conditions. The effect of the controllable pitch propeller on the engine is analogous to that of the gear shift for the automobile, and the controllable pitch propeller has sometimes been referred to as the "gear shift of the air."

A large part of the early pioneering development on the controllable pitch propeller was carried out at the aeronautical

laboratory of the U.S. army at McCook Field, Dayton, O. These experiments led to the adoption of the detachable aluminum alloy blades for the propellers. While the pitch of these early propellers could not be changed in flight, the development of the aluminum alloy blade paved the way to a large degree for the later development of the controllable pitch propeller

A large number of types of controllable pitch propellers were built experimentally The Hamilton standard is one of the leading successful controllable pitch propellers, and may be taken to indicate the development of this adjunct to flying The original of this type was built in late 1929, and improvement was rapid after that time During 1933, the Hamilton standard came into universal use on the air transport lines of the United States, and the propeller was awarded the Collier trophy for the greatest advancement in aviation during that year.

This propeller is made with semihollow aluminum alloy blades journaled at the end on plain bearings. Centrifugal load on the blades is taken up by means of roller bearings encircling the inner ends of the blades. The actual operation of changing the pitch is carried out by means of an oil cylinder which forces the blades into the low pitch position when oil pressure is applied When the oil pressure is released, the propeller is forced into high pitch by means of counterweights which are acted on by centrifugal force.

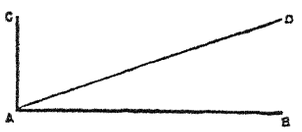

FIG. 2

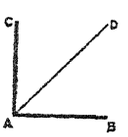

FIG. 3

FIGS. 2 AND 3.—DIAGRAM SHOWING THE MOVEMENT OF A POINT NEAR THE TIP OF THE BLADE AND NEAR THE BOSS OF THE AIRSCREW

AB = Velocity of rotation. AC = Velocity of forward motion. AD = Resultant velocity

The device is very simple in design and in operation. In the initial form, it utilized two pitch settings, one being suitable for take-off and climb, and the other for level flight and cruising. The latest development of the device incorporates an automatic governor which serves to change the pitch automatically so as to maintain the engine operation at any constant number of revolutions per minute which may be selected by the pilot in flight. This device is known as the constant speed propeller.

**Materials of Construction.**—At first airscrews were invariably constructed of hardwoods, such as walnut or mahogany. The blades were built up of a number of superimposed planks or laminae about one inch thick, suitably cut to shape. In fig. 1 the cut planks for a two-bladed airscrew are illustrated. The planks are glued together to form the rough block from which the airscrew is shaped. This and the finished airscrew are also shown.

Wooden airscrews are affected by the humidity and temperature of the atmosphere, and have been found unsuitable for tropical climates. Hence there has arisen a need for metal airscrews. Of such there are two distinct types: airscrews with hollow blades, and those with solid blades. The former are constructed of steel and the latter of a light metal, usually an aluminum or magnesium alloy. Both types have met with a considerable degree of success, but both are heavier and more costly than the wooden airscrew. Despite the added expense, however, metal propellers have come into very common use, particularly on engines of higher horsepower In large sizes the weight of the solid type appears likely to be excessive, while that of the hollow steel type approaches very closely to that of a wooden airscrew.

**AIRSHIP,** a self-propelled dirigible aircraft, inflated with a gas lighter than air and sustained aloft chiefly by buoyancy from aerostatic forces. To distinguish it from the free balloon or balloon which has similar lighter-than-air flight characteristics but no propelling or steering system, the airship is sometimes popularly referred to as a dirigible balloon or dirigible.

Consisting of an elongated gas-filled streamlined hull, mounting one or more cars or gondolas, power plants and stabilizing fins with attached rudder and elevator control surfaces, airships are classified according to three structural types: nonrigid, semirigid and rigid.

The hull of a nonrigid airship, the so-called blimp type, consists of a gas-tight fabric envelope which maintains its form by the pressure of the lifting gas and air ballonets (which inflate and deflate to compensate for changes in gas volume) contained therein. The semirigid airship similarly depends upon internal gas and air pressure to sustain the form of its envelope but has in addition a supporting metal keel extending longitudinally along the bottom of the ship. Because of their reliance upon a pressure differential for the maintenance of envelope rigidity, nonrigids and semirigids are also known as pressure airships This distinguishes them from the rigid airship, the hull of which, consisting of a rigid structural frame, maintains its shape irrespective of internal gas pressure. Around this framework of girders, an outer cloth covering is secured, and, inside, individual gas cells are arranged throughout the ship's length.

## EVOLUTION OF THE AIRSHIP

Human flight was first made possible in 1783 by the invention of the free balloon, and there immediately followed a period of intensive balloon development (see BALLOON). The airship was the inevitable result of [illegible] and of man's desire to construct an aircraft which could be propelled and steered. Accordingly, from 1783 to 1852, when the first airship was flown, numerous unsuccessful attempts were made to propel and steer balloons. These efforts failed primarily because of lack of a suitable mechanical means of propulsion and the consequent dependence upon oars and other primitive types of manual power.

Finally in 1851, Henri Giffard, the French inventor of the steam injector, overcame the airship power plant problem by developing a 350 lb. steam engine of 3 h.p. which could drive a propeller 11 ft. in diameter at 110 r.p.m. The following year, he constructed an 88,000 cu.ft. airship, 144 ft. long and 40 ft. in diameter, and mounted his engine thereon. Giffard ascended in this hydrogen-filled craft on Sept. 24, 1852, from the Hippodrome in Paris and, at an estimated speed of 6 m.p.h., demonstrated in a light wind the first appreciable control ever exerted on a lighter-than-air craft.

Initial application of the internal-combustion engine to airship flight was made by the German engineer, Paul Haenlein, when in 1872 he completed and flew an airship propelled by a gas engine drawing its fuel from the envelope. The French brothers Albert and Gaston Tissandier were the first to build an electrically powered airship; their 37,500 cu.ft. craft, powered by a

1.5 h.p. electric motor, made a successful initial flight on Oct. 8, 1883.

The first airship to possess sufficient control enabling it to return to the point of ascent was the electrically powered 66,000 cu.ft. "La France," constructed of an envelope of Chinese silk and a car of bamboo trelliswork. Powered by an 8 h.p. electric motor and piloted by its constructors, Charles Renard and A. C. Krebs, this French airship made its first trial on Aug. 9, 1884, at Chalais-Meudon and completed a circular flight of about five miles. By this and subsequent similarly successful flights, the "La France" demonstrated to the world the practicability of airship navigation.

The 130,000 cu.ft. David Schwarz aluminum-hulled airship, built and tested in Germany in 1897, was the first airship of the rigid type. Consisting of an aluminum framework covered by aluminum sheeting, it was also the first airship powered by a gasoline engine. Although the craft failed on its initial flight because of gas leakage and faulty power transmission, it was noteworthy for having introduced the rigid and metal-clad principles to airship construction.

Meanwhile, Albert Santos-Dumont, a Brazilian living in Paris, had become interested in lighter-than-air flight, and in 1898 completed his first in a series of 14 nonrigid, gasoline-powered airships. These small Santos-Dumont ships performed a number of record-making and unusual flights which won world-wide fame for their constructor. In 1905, Santos-Dumont abandoned airship development to turn his inventive genius to heavier-than-air craft.

An event of great importance was the construction of the first Zeppelin airship (LZ-1) which made its initial flight from a floating hangar on Lake Constance, Germany, on July 2, 1900. Designed by Count Ferdinand von Zeppelin, a German army officer who had retired to devote his full-time efforts to the development of a radically different airship of rigid structural design, the 388,410 cu.ft. LZ-1 was 420 ft. long and 38 ft. in diameter. Its cigar-shaped aluminum frame consisted of 24 longitudinal girders extending from nose to tail, spaced by 16 transverse rings, and braced by diagonal wiring. The entire frame was covered by a cotton cloth to protect the inner structure and to present a smooth outer surface. Inside the framework, between the transverse rings, were separate hydrogen-filled gas cells of rubberized cloth, while, under the craft, was a keel-like structure connecting two external cars. In each of the cars was a 16 h.p. engine geared to two propellers. A sliding weight secured to the keel was designed to afford vertical control by raising or lowering the nose; rudders were provided for horizontal control. Despite structural weaknesses, the LZ-1 proved the practicability of the Zeppelin design and attained speeds approaching 20 m.p.h. In constructing subsequent airships, Zeppelin experienced numerous financial reverses and accidents which threatened to end his aeronautical activities; popular subscription and later governmental support, however, enabled the development of the Zeppelin airship to continue uninterruptedly until the end of World War I.

During the first decade of the 20th century, airship construction was carried on in most of the major countries of the world. Such development was at first generally limited to private enterprise and to the efforts of aeronautical sportsmen and inventors. However, as these pioneering efforts began to meet with success, governmental interest arose, and the employment of the airship as a war machine soon followed.

During World War I, airships saw considerable use by the major belligerents. Germany's Zeppelins, developed by that time to a point of great strength, large load carrying ability and high performance characteristics, operated with the Imperial German army and navy. Military and naval missions were flown by French pressure airships, while similar war duties were performed by Italian semirigids. Great Britain and the U.S. looked to their nonrigids for a solution to the U-boat problem. Given the impetus of war, the airship underwent unprecedented development from 1914 to 1918. Zeppelins were produced at the rate of one every two weeks; nonrigids were built which could make routine flights of 30 hr. and more; all phases of airship construction, operation, maintenance and ground handling were improved.

The treaty of Versailles prohibited the Zeppelin company from undertaking further airship construction and directed the delivery of existing Zeppelins and hangars to the victorious Allied powers. With these Zeppelins and with other rigid airships of their own design and construction, France, Great Britain and the U.S. undertook rigid airship programs which during the 1920s and early 1930s constituted an important part of their national aeronautical activity. The loss, however, of France's "Dixmude" (1923), Britain's R-101 (1930) and the United States' "Macon" (1935) led to the abandonment of rigid construction and operation by these countries. French and U.S. airship activity was thereafter limited to the operation on a reduced scale of small nonrigids or semirigids, while Great Britain terminated its airship program in its entirety. The abandonment of rigid airships by these three nations left Germany, whose Zeppelin company had re-entered the airship field by constructing the U.S. navy's reparations dirigible "Los Angeles" (1924) and the commercial ships "Graf Zeppelin" (1928) and "Hindenburg" (1936), as the sole constructor and operator of the rigid type of craft.

The period immediately preceding World War II witnessed the destruction by hydrogen fire in 1937 of the Zeppelin company's "Hindenburg" and the completion in 1938 of its sister ship, the new "Graf Zeppelin." At the outbreak of World War II in 1939, only two nations were positively known to possess airships. The U.S. was operating nonrigids for coastal patrol; Germany possessed the old and new "Graf Zeppelin." France had discontinued its airship service in 1937, and nothing had been heard after 1938 of Russian activity, about which previously little had definitely been known.

As the war progressed, nazi directives ordered the dismantlement of Germany's two airships, and Allied bombings in 1944 destroyed the Zeppelin company's hangars and production facilities. While the war ended Germany's airship activity, it provided a great stimulus to that of the U.S. The U.S. navy, realizing the antisubmarine value of the blimp (popular term for nonrigid airship), embarked upon a lighter-than-air expansion program which resulted in the operation of almost 200 blimps from bases in North and South America, Europe and Africa.

The post-World War II period of aeronautical development began with only two nations, the U.S. and the U.S.S.R., engaged in airship activity. Soviet lighter-than-air operations were disclosed in late 1945 by press releases reporting flights by the airship "Victory," while the completion of another ship, the "Patriot," was announced in Nov. 1946. The U.S. navy's airship service, meanwhile, was continued on a reduced peacetime scale with an emphasis upon training and experimentation and with antisubmarine or utility services to the U.S. fleet being provided by operational blimp squadrons.

United States civil airship activity was resumed with the operation of blimps by three concerns for commercial or advertising purposes.

## DEVELOPMENT OF AIRSHIPS BY NATIONS

The development of the airship was international and primarily reflected the lighter-than-air efforts of Germany, Great Britain, France, the U.S. and, in the 1930s, of the U.S.S.R. Other nations, however, including Italy, Spain, Poland, Switzerland and Japan, engaged in airship operations at one time or another, but their activity and therefore their accomplishments in this field were limited.

**Germany.**—Although the success of the rigid airships of Count Zeppelin's Luftschiffbau-Zeppelin company dominated the German lighter-than-air picture, there were nevertheless other German dirigible constructors. Maj. August von Parseval in 1906 constructed for the German army the first in a series of some 28 Parseval pressure type airships which were built from that date until 1929. In 1907, a semirigid airship was constructed for the imperial German government by Maj. von Gross and Nikolas Basenach. Some four additional Gross-Basenach ships were built; the last, completed in 1913, had a speed of 51 m.p.h. and saw service with the German navy in the Baltic sea.

Count Zeppelin's competitors in German rigid airship development were Johann Schütte and Heinrich Lanz who in collaboration evolved a rigid design, using a spirally disposed wooden girder type of construction. Their first ship, a 700,000 cu.ft. capacity, 430-ft.-long, 60-ft.-wide craft, was completed in 1911 and attained a speed approaching 50 m.p.h. The last Schütte-Lanz airship (22nd in the series) was completed in June 1918.

Meanwhile, the success of the Zeppelin type had led to the foundation in 1910 of the Deutsche Luftschiffahrts-Aktien-Gesellschaft, commonly known as Delag, which was a transportation company organizing commercial and pleasure flights in airships until the outbreak of World War I in 1914. During these five years, Delag's five Zeppelins made about 1,600 flights, carrying 37,250 passengers without injury.

During World War I, 88 Zeppelins were built at four Zeppelin fabrication plants. These ships operated under the German army and navy for North sea patrol, scouting and for bombing of strategic areas, although they were gradually rendered ineffective in the latter mission by improvement of Allied defense means. Under the pressure for greater range and larger bomb loads and in order that they might fly higher and faster, the Zeppelins underwent remarkable improvement during this period. By 1918, size had increased to 2,400,000 cu.ft., speed to 80 m.p.h., useful lift to 50 tons, and ceiling to more than 20,000 ft. The Zeppelins were armed with machine guns mounted in the cars and atop the hull; they also had a subcloud car which could be lowered beneath the clouds. An observer in this car could navigate or direct bombing while the airship remained hidden above. (*See* AIR RAIDS.)

Zeppelin activity temporarily ceased with the capitulation of Germany in 1918. Existing Zeppelins were sabotaged by their crews, dismantled or delivered to France, Italy, England, Belgium and Japan. Two small commercial Zeppelins, the "Bodensee" and "Nordstern," were built immediately following the Armistice, but were surrendered to Italy and France respectively in 1921.

The next Zeppelin airship was the 2,470,000 cu.ft. LZ-126 which was constructed as a war reparations payment to the U.S.; this airship, later christened the "Los Angeles," was delivered to the U.S. by a transatlantic flight in Oct. 1924. The "Graf Zeppelin" (LZ-127), a 3,708,600 cu.ft. ship, was completed in Sept. 1928; this airship saw nine years of successful continuous service. When decommissioned in 1937, the "Graf Zeppelin" had made 590 flights (including 144 ocean crossings) and had flown 1,053,391 mi., carrying 13,110 passengers and 235,300 lb. of mail and freight. Hugo Eckener, successor to Count Zeppelin who died in 1917, commanded the ship on a 21,700 mi. world flight, completed in an elapsed time of 20 days and 4 hours in 1929. (*See* also TRANS-OCEANIC AND TRANS-CONTINENTAL FLIGHTS.)

The LZ-128 did not progress far beyond the blueprint stage and was followed by the 7,063,000 cu.ft. "Hindenburg" (LZ-129), completed in 1936. This 803-ft.-long airship, of conventional Zeppelin design with 36 longitudinal girders and 15 wire-braced main transverse frames, was powered by four 1,100 h.p. Mercedes-Benz diesel engines which gave the ship a maximum speed of 84 m.p.h. At a cruising speed of 78 m.p.h., the "Hindenburg," which contained accommodations for 50 passengers within its hull, had an 8,750 mi. range. In 1936, this airship operated the first commercial air service across the North Atlantic by carrying 1,002 passengers on 10 scheduled round trips between Germany and the U.S.; eastbound crossings averaged 65 hr., westbound, 52 hr. On May 6, 1937, while landing at Lakehurst, N.J., on the first of its 1937 season of North Atlantic crossings, the hydrogen inflated "Hindenburg" burst into flames and was completely destroyed with a loss of 36 lives—including the first passenger fatalities in the history of commercial airship operation. The fire was generally attributed to a discharge of atmospheric electricity in the vicinity of a hydrogen leak.

The LZ-130, bearing again the name "Graf Zeppelin" was completed and tested in Sept. 1938. Designed for helium operation, this slightly modified sister ship of the "Hindenburg" was built for transatlantic commercial service, but the tense international situation at that time and the refusal of the U.S. to export helium prevented the use of the ship for such a purpose. Inflated with hydrogen, the LZ-130 made a limited number of exhibition and test flights over Germany but saw no commercial or war service.

With the completion of the LZ-130 in 1938, work was begun on the LZ-131 but, as the outbreak of World War II approached, the German government in July 1939 directed the Zeppelin company to discontinue all lighter-than-air manufacture. Finally, in April 1940, another nazi directive ordered the dismantlement of the LZ-130, the old decommissioned "Graf Zeppelin" (LZ-127) and the main Zeppelin operating terminal at Frankfurt-on-Main; the reason given was the war need for duralumin and steel. Later, in July 1944, Allied bombings of Friedrichshafen resulted in the destruction of the hangars, shops and production facilities of the Zeppelin company, then engaged in the production of miscellaneous war materials.

**Great Britain.**—Prior to World War I, the British made little contribution to airship development, although a few private experimenters, notably Henry Spencer, Dr. Barton and E. T. Willows, aroused sufficient interest to cause the government to begin airship construction in 1907. From that date to the outbreak of hostilities in 1914, about eight British pressure airships, varying in volume from 21,000 to 180,000 cu.ft., were constructed, while an additional five were purchased from France and Germany. A rigid, the 660,000 cu.ft. "Mayfly," designed along Zeppelin lines, was completed in 1911; this ship never flew because it broke in two the same year while being brought out of its shed at Barrow. The failure of the "Mayfly" temporarily halted British rigid airship construction until 1914.

During the war period of 1914–18, seven nonrigid types were evolved for antisubmarine, antimine and coastal patrol duties. Ranging in size from the 60,000 cu.ft. S.S. type to the 360,000 cu.ft. North Sea class, these airships attained speeds as high as 58 m.p.h. and one, the NS-11, made a flight of 101 hr. endurance in 1919. A total of 207 nonrigid airships was built or used by Great Britain from 1914–18; of this number, 56 were in active service from June 1917 to Oct. 1918, during which time they flew 59,704 hr. and sighted 49 submarines. More than 9,000 patrol and 2,200 escort missions were carried out from 17 airship stations and 12 mooring-out sites. Nonrigid activity ceased shortly after the termination of the war, but one commercial blimp, the 60,000 cu.ft. AD-1, was constructed in 1929.

Rigid construction was resumed in 1914 when work was begun on the R-9; this second British rigid was completed three years later. Six rigids (two modified to abolish external keels) of the R-23 class were next laid down, followed by the R-31 and R-32, which were of wooden construction. None of these airships, however, equalled the products of the experienced Zeppelin designers and constructors. When the German Zeppelin L-33 was shot down in good condition over Essex in 1916, it served as a model for the next British rigids, the R-33 and R-34 which were completed in 1919 and were marked in their improvement in construction and performance; in fact, the R-34 had sufficient range to complete a transatlantic flight to Mineola, N.Y., the same year —the first transoceanic airship flight. Two additional rigids, the R-80 and R-36, were launched in 1920 and 1921. They were followed by the 2,700,000 cu.ft. R-38, which was to be purchased by the U.S. navy. Delivery by air was planned, but on its fourth trial flight, on Aug. 24, 1921, the craft broke in two and fell into the Humber river, killing 44 British and U.S. airship officers and men. The R-38 disaster brought British service airship activity to a halt, but in 1924 there was undertaken an empire communications scheme which provided for the construction of two commercial 5,000,000 cu.ft. rigid airships, the R-100 and R-101. Both were completed in 1929, the former by the Airship Guarantee company at Howden, the latter by the Royal Airship works at Cardington. The R-100, with accommodations for 100 passengers, was built on a modified Zeppelin design with six gasoline engines. Its two-year life was uneventful, although in July 1930 it flew to Montreal, Quebec, in 78 hr., returning the following month in 58 hr. The R-101, which was lengthened subsequent to completion to increase its lifting capacity, accommodated about 50 passengers

and deviated substantially from Zeppelin practice by using steel girders and five diesel engines. On an attempted flight, Oct. 5, 1930, to India, the R-101 crashed into a hill during a storm near Beauvais, France, and burst into flames, killing 46 persons. Following this disaster, the government scrapped the R-100 in 1931 and abandoned airship activity indefinitely.

**France.**—In spite of the broad French background in early lighter-than-air development, French interest lapsed appreciably after A. Santos-Dumont demonstrated his series of airships. The first significant modern airship of native French design was the Lebaudy brothers' "Jaune" (1902), which resulted in an order from the ministry of war for a slightly larger version. The success of the Lebaudys encouraged others to undertake lighter-than-air manufacture. From 1904 until the outbreak of World War I, pressure airships for the French government, for private use and for export were constructed in appreciable numbers by the Astra, Clément-Bayard, and Zodiac firms and by the government's airship factory and development centre at Chalais-Meudon.

During World War I, about 30 airship types were produced, with capacities ranging from 70,600 cu.ft. to 501,100 cu.ft. The French army, which had possessed about 16 airships during the war period, abandoned its airship activity in 1917, transferring 8 ships to the navy for operation. With an additional 52 airships, the French navy in 1917–18 performed more than 3,300 flights totalling 16,000 hr.; these airships were said to have attacked 60 U-boats and sighted 100 mines.

After the Armistice, considerable governmental interest was shown in rigid airships, of which type only one had previously been constructed in France. This had been the none too successful "Spiess," a privately owned wooden rigid built by the Zodiac society in 1912. Three Zeppelins, the L-72, LZ-113 and the small commercial "Nordstern," were turned over to France by Germany in 1920–21. The latter two saw little active service prior to dismantlement, but the 2,470,000 cu.ft. L-72 (renamed the "Dixmude" by the French) established an endurance record of 118 hr. 41 min. in Sept. 1923. In December of the same year, the "Dixmude" was lost over the Mediterranean with its entire complement; this disaster brought about the termination of rigid activity in France.

Despite the loss of the "Dixmude," French naval nonrigid and semirigid airship activity continued. From the end of World War I to its disestablishment in 1937, the French naval airship service operated an average minimum of two ships without a serious accident or fatality; the main operating base was Rochefort. All airships built during this period were constructed by the sole remaining French airship manufacturer, the Zodiac society, which from 1924–37 produced ten airships (six nonrigid, four semirigid) for the navy; the smallest was a 130,000 cu.ft. Vedette, the largest a 350,000 cu.ft. Escorteur.

In 1936, Zodiac developed for the French army a 35,000 cu.ft. motorized observation balloon with an attachable power and control gondola, so that it could be flown as an airship to alternative positions. This balloon went into mass production in May 1940, during which month 21 were completed. Additional motorized balloons were not produced because of the defeat of France the following month, but several were subsequently seized by the Germans for use against the U.S.S.R. The termination of navy airship activity by government decree in 1937 and of similar army activity by German conquest in 1940 was made all the more complete by Allied bombings of airship hangars and by other war destruction. French post-World War II aviation plans therefore included no provisions for lighter-than-air development; no governmental or private airship construction was planned although the sport of free ballooning was revived in 1945–46 to such an extent that the manufacture of balloons was recommenced by Zodiac.

**Italy.**—Most Italian airship construction concerned itself with the development of the semirigid type, in which Italy was soon acknowledged to be the leader. Several P- and M-type airships, 166,000 cu.ft. and 424,000 cu.ft. respectively, were designed and built by Gen. A. Crocco and Ricaldoni prior to World War I; several Forlanini type semirigids had similarly been completed by the beginning of hostilities. During the World War I period of 1914–18, additional types were developed, primarily to increase altitude performance for bombing missions.

Although receiving three Zeppelins from defeated Germany in 1920–21, the Italians made little or no effort to explore the possibilities of the rigid airship; indeed, improper handling resulted in wrecking two of these Zeppelins before they had been in Italian possession one year. In 1921, a 1,240,000 cu.ft. semirigid, the "Roma," was sold to the U S. army; this 410-ft.-long airship was shipped disassembled to the U.S. where it was re-erected. During a test flight on Feb. 21, 1922, the "Roma" became unmanageable, crashed into a high tension wire and burned, killing 34 persons. The well-known N-type Italian semirigid was developed by Gen. Umberto Nobile and was the last airship type undertaken under government cognizance when Italy officially terminated its airship program in 1927. On May 11, 1926, the 654,000 cu.ft. "Norge" (N-1), carrying an expedition headed by Roald Amundsen, Lincoln Ellsworth and Nobile, left Spitzbergen for the north pole. The "Norge" passed over the pole on May 12 and, continuing its 3,000-mi. flight, landed 2 days later at Teller, Alaska, where it was dismantled. The N-3, third of the Nobile N-series, was sold to Japan where it was destroyed during naval manoeuvres in Oct. 1927. Using the "Italia" (N-4), Nobile attempted another polar flight in May 1928, but after reaching the north pole, the ship crashed on its homeward journey with a loss of seven lives. The "Italia" affair and its unpleasant repercussions signalled the end of airship development in Italy, and Nobile later went to Russia to practise his art of semirigid airship design.

**Russia.**—Although Russia had shown a pre-World War I interest in airships by purchasing semirigids from France, there was little concerted activity until about 1931 when a public subscription of 15,000,000 rubles toward an airship program was announced. The second five-year plan provided for the operation of airships on civil air routes within the Soviet Union, and to assist this program the services of Gen. Umberto Nobile, Italian designer of semirigid airships, were secured. A number of small pressure airships were subsequently constructed, and in 1933 plans were announced to lay down a 1,304,620 cu.ft. commercial ship at Dolgo Prutnaja, 19 km. from Moscow, and one of 705,200 cu.ft. at Leningrad. The former, like the 2,820,000 cu.ft. metal-clad also announced as planned, was presumably never built. The Dirigiblestroi or Dirigible Construction trust in 1936 began the 353-ft.-long 882,829 cu.ft. semirigid DP-9. In 1937 a Russian airship commission visited the U.S. to study American airship efforts. In September of the same year, the 650,000 cu.ft. semirigid V-6 established an endurance record of 130 hr. 27 min. (This record stood until Nov. 1946 when it was broken by 40 hr. by the U.S. navy blimp XM-1.) The V-6 was destroyed with the loss of 13 lives in 1938 when it crashed into a mountain while participating in rescue operations to assist soviet scientists marooned on a drifting polar ice flow. In May 1938, the V-10 began its trials at Moscow, and the V-8 was reportedly still under construction for a proposed commercial route between Moscow and Leningrad.

Nothing was heard of Russian lighter-than-air activity during World War II. In late 1945 it was disclosed that a small civil airship, the "Victory," had made an 80 hr. demonstration flight over the Black sea. In Nov. 1946, the existence of another soviet airship, the "Patriot," was announced; this 150-ft.-long craft was reported to be dual engined and capable of carrying 12 passengers with a 1-man crew. Helium resources exist in the U.S.S.R. and it was probable that this noninflammable gas was being used as an inflation medium for soviet airships.

**United States.**—A number of small privately-owned pressure airships were built and flown by Capt. Thomas S. Baldwin, Lincoln Beachey and Roy Knabenshue immediately following the beginning of the 20th century. The first practical U.S. airship was Baldwin's "California Arrow" (1903), while the first U.S. government airship was a 19,500 cu.ft. craft bought from Baldwin by the U.S. army in 1908. Two unsuccessful attempts to fly to the north pole were made in 1907 and 1909 by the explorer Walter Wellman in his airship "America"; using the same craft, Wellman in 1910 attempted a transatlantic flight which similarly failed. In

1912, Melville Vaniman took off from Atlantic City, N.J., for a transatlantic flight in the "Akron," but within 15 min. after departure, the airship caught fire and was destroyed with the loss of its entire crew of 5.

Naval airship activity began when the 175-ft.-long, 114,800 cu.ft. capacity, DN-1 was contracted for in 1915. Erected in a floating hangar at Pensacola, Fla., the DN-1 (later redesignated the A-1) was completed in April 1917; the craft proved unsatisfactory because of excessive gas leakage and was abandoned after three flights.

In 1917, with war clouds on the horizon and serious attention being given to the development of nonrigids for antisubmarine and coast patrol duties, the navy ordered 15 B-type airships (77,000 to 84,000 cu.ft.), which were completed in 1917–18 by the Goodyear Tire and Rubber company, Goodrich Tire and Rubber company and Connecticut Aircraft company. The B-class was followed by the 182,000 cu.ft. C-type, for which 30 (reduced to 10 after the Armistice) were contracted with Goodyear and Goodrich; the first C-ship was completed in Sept. 1918. During U.S. participation in World War I, U.S. navy blimps were based at seven Atlantic coast air stations from Chatham. Mass., to Key West, Fla., while other airships, acquired from the French, were operated from Paimboeuf, France. In May 1919, the C-5 attempted a transatlantic crossing; after flying from Montauk, Long Island, N.Y., to Newfoundland in 23 hr., the blimp was lost when strong winds tore it away crewless from its mast and blew it to sea.

Five D-type airships (189,000 cu.ft.) were next built by Goodyear and Goodrich. A considerably modified D-ship, the D-6, was later produced by the navy. In 1918 and 1919, Goodyear built three small, single engine, nonrigid airships, of which two, designated the E-1 and F-1, were purchased by the navy. A 400,000 cu.ft. G-ship design was completed in 1919, but no ships of this type were constructed. The designation G was later applied to a class of utility and training ships (183,000 to 196,700 cu.ft.) which began with the G-1 (ex-Goodyear "Defender") acquired in 1935. The first and only navy semirigid airship was the O-1, erected at Cape May, N.J., in Sept. 1919; imported from Italy, this craft saw only three months' service. In 1921, Goodyear completed for the navy the 43,000 cu.ft. H-1, a single engine airship which could be towed or used as a kite balloon. The next naval airship type was the J-ship, of which the first unit was completed in 1922.

Meanwhile, the U.S. army, which had no World War I airship program, undertook such development in 1919, with a joint services agreement that its program would concern itself with nonrigid and semirigid development, while the navy would concentrate on rigid airship activity. The army acquired several blimps from the navy and constructed main airship bases at Langley Field, Va., and Scott Field, Ill. A number of nonrigids, particularly of the TC-class, were constructed for the army which, in addition, to investigate the semirigid design, purchased the "Roma" from Italy in 1921 and the 719,000 cu.ft RS-1 from Goodyear four years later. The 1,240,000 cu.ft. Italian-built ship was destroyed with the loss of 34 lives on Feb. 21, 1922, when it burned after striking a high tension wire at Langley Field, Va. The RS-1, after several years of intermittent service, was dismantled, and the army concentrated thereafter on nonrigids and motorized balloons. Finally, in 1937, the army terminated its airship program and turned over its nonrigids to the navy.

Entrusted with rigid airship development, the navy began construction of the 2,115,174 cu.ft. ZR-1 in 1919. Fabricated at the Naval Aircraft factory, Philadelphia, Pa., and assembled at the Naval Air station, Lakehurst, N.J., this ship, christened the "Shenandoah," was largely a copy of the German Zeppelin L-49 design, modified for mooring mast and helium operation. Her maiden flight on Sept. 4, 1923, was followed by a number of noteworthy flights including a 9,000 mi. transcontinental trip. On Sept. 3, 1925, the "Shenandoah" broke into three parts in a line storm over Ohio, killing 14 members of her crew of 43.

That no fire accompanied the "Shenandoah's" destruction, thereby enabling 29 crew members to free balloon the hull sections to earth, was undoubtedly due to the noninflammable helium with which the ship was inflated. Helium had been adopted as the sole inflation medium of army and navy airships following the burning of the former's hydrogen filled "Roma" in 1922. The first U.S. airship inflated with helium had been the army's C-7 in Dec. 1921.

The purchase of the British rigid R-38 (U.S. navy designation, ZR-2) was authorized in 1920 with accompanying arrangements for the instruction of U.S. personnel in British rigid airship technique. This 2,700,000 cu.ft. ship was destroyed on Aug. 24, 1921, with the loss of 16 U.S. airship officers and men when it broke in two during its fourth trial flight in England.

On Oct. 15, 1924, the German Zeppelin company delivered the 2,470,000 cu.ft. ZR-3, later christened the "Los Angeles," to Lakehurst, N.J., after a 5,000 mi. flight from Friedrichshafen where the ship had been constructed as a war reparations payment to the U.S. This 658-ft.-long dirigible was used extensively for experimental work on flight and mooring problems and developed a means for hooking-on and releasing aeroplanes in flight. After 331 flights for a total of 4,320 hr., the "Los Angeles" was decommissioned at Lakehurst in 1932 and dismantled 7 years later.

The German Zeppelin patents and processes together with the services of key Zeppelin personnel were acquired in 1924 by the Goodyear Tire and Rubber company, which formed a subsidiary, the Goodyear-Zeppelin corporation, in Akron, O. In 1928, Goodyear-Zeppelin began the construction of two 6,500,000 cu.ft. rigid airships for the navy. Both ships were 785 ft. long and 133 ft. in diameter, with a cruising range of 6,500 mi. and a maximum speed of 72 knots. The power plant installation was novel, with each ship having eight 560 h.p. Maybach engines mounted in separate engine rooms within the hull and driving propellers so mounted on outriggers that they could be swivelled to produce a vertical lifting component. To compensate for weight lost through fuel consumption, water recovery apparatus was installed with exhaust condensers mounted on the hull above the engine rooms. Each ship also carried a trapeze for the landing and launching of aeroplanes and possessed an internal hangar for five planes. The "Akron" (ZRS-4) was completed in 1931 but, after about 1,200 hr. of service, crashed with the loss of 73 lives on April 4, 1933, in a storm off the New Jersey coast. Her sister ship, the "Macon" (ZRS-5), was launched the same month and operated primarily from the new airship base at Sunnyvale, Calif.; previous rigids had all been based at Lakehurst. On Feb. 12, 1935, while returning from fleet manoeuvres, the "Macon" suffered failure of her upper fin structure, resulting in loss of control. With severe gas leakage and accompanying structural collapse, the "Macon" settled to the sea and slowly sank off the California coast; all but two crew members were rescued.

The loss of the "Macon" left the navy without an operational rigid airship and led to numerous naval, governmental and civil investigations to determine the safety and practicability of rigid airships. Since the results of these investigations endorsed further dirigible construction, a 3,000,000 cu.ft. navy rigid was authorized in 1938. However, money appropriated by congress to begin its construction reverted to the treasury after delays in selecting the design and size; subsequent funds were not voted, and the ship never progressed beyond the drawing board stage.

In the period between World Wars I and II, United States civil airship activity was primarily limited to the operation of commercial and advertising blimps by the Goodyear company, constructor of virtually every significant U.S. airship after 1911. After experimenting with a small "pony blimp," Goodyear in 1925 began the operation of from one to six of its own nonrigid helium inflated airships, which pioneered many airship flight and ground handling improvements. The capacity of these Goodyear blimps varied from 51,000 cu.ft. to 183,000 cu.ft. but was later standardized at 123,000 cu.ft., a size which carried 6 passengers. From the beginning of these commercial operations in 1925 until the transfer of the Goodyear blimp fleet to the navy in 1942 for war duty, Goodyear airships made 152,441 flights and carried 407,171 passengers without a single passenger injury or fatality.

In 1935, with rigid airship activity ended by the crash of the "Macon," naval lighter-than-air efforts again centred about nonrigid development. At that time, the navy was operating the 210,000 cu.ft. J-4, the 320,000 cu.ft. K-1, and the 202,000 cu.ft. ZMC-2. The J-4 was an open gondola ship completed in 1924, while the K-1, completed in 1931, used Blau gas as well as gasoline for fuel. The ZMC-2, first successful all metal airship, was constructed in 1929 by the Metalclad Airship corporation of Detroit, Mich. Its hull consisted of 24 longitudinals and 12 circular frames to which an .0095 in. thick outer cover of alclad sheet was riveted. Although possessing certain rigid construction characteristics, the ZMC-2 was nevertheless a pressure airship depending upon internal pressure to maintain hull rigidity in flight. While the craft had a long successful life prior to dismantlement, no other metal-clads were built. The 183,000 cu.ft. Goodyear-owned "Defender" was acquired by the navy in 1935 and designated the G-1. Two years later, upon abandonment of the army airship program, the navy received the former army TC-13 and TC-14, nonrigids of about 350,000 cu.ft. capacity.

Increased airship strength was authorized as the entry of the United States into World War II drew near, and at the time of Pearl Harbor the navy was operating 4 new K-type patrol airships (built 1938–41), 3 small L-type trainers (built 1938–41), the G-1 and the TC-13 and 14. The airship building program was speeded up and an improved G-type and new M-type ship evolved. During the war period, the navy operated a total of 134 K-type (425,000 cu.ft.) and 4 M-type (647,500 cu.ft.) patrol airships, 22 L-type training ships of 123,000 cu.ft. capacity and 8 G-type (196,700 cu.ft.) training and utility blimps.

Except for those used primarily for training and experimentation, U.S. navy airships of World War II were grouped into 14 U.S. fleet blimp squadrons which, operating from more than 50 main and auxiliary bases, performed antisubmarine patrol and escort operations in a 3,000,000 sq.mi area along the U.S. Atlantic, Gulf and Pacific coasts, in the Caribbean, along the South American coast from Panamá to Rio de Janeiro and in the Mediterranean. A U.S. fleet blimp utility squadron similarly operated from five bases along the Atlantic seaboard. These 15 squadrons flew a total of 55,900 flights for 550,000 hr. and escorted 89,000 ships without the loss of a single vessel to enemy action. Of the blimps assigned to fleet units, 87% were in operational readiness at all times, thereby establishing a record availability for military aircraft.

The year 1944 marked the peak of World War II airship operation; at that time, naval lighter-than-air flight personnel numbered 1,500 officer pilots and 3,000 enlisted air crewmen; ground administrative and maintenance personnel amounted to 706 officers and 7,200 enlisted men.

The first nonrigid airship transoceanic flight was made in 1944 when blimp squadron 14 was ordered based with six K-ships at Port Lyautey, French Morocco, for patrol of the Straits of Gibraltar. The blimps were ferried across the Atlantic in pairs from South Weymouth, Mass., via Newfoundland and the Azores. The first flight (3,145 mi.) was made on May 29–June 1, 1944, by the K-123 and K-130 in a total flight time of 58 hr. In 1945, two additional K-ships were flown to Port Lyautey from Weeksville, N.C., via Bermuda and the Azores; the 3,532 mi. flight was completed in a flight time of 62 hr. Another transatlantic airship movement was planned in May 1945 when the navy, recognizing the value of the airship in visual and instrumental detection of U-boats, ordered a blimp squadron based in southwest England. This move was cancelled just prior to execution because of the capitulation of Germany.

Although antisubmarine operations were the main duties of U.S. navy airships during the war, it was found that their unusual flight characteristics were valuable in the fulfilment of general utility missions. Torpedo recovery, aerial photography, observation, special equipment calibration, search operations, rescue work and other services requiring slow speed, low altitude operations for extended periods of time were performed in great numbers and variety for fleet and shore units. In the Mediterranean, the airships of squadron 14 assumed an unprecedented importance in mine sweeping operations through spotting and marking otherwise undetected mine fields and through saving a number of sweeping vessels by diverting them from collision courses with mines they could not see.

With the end of hostilities in 1945, the active naval airship organization was reduced to two operational U.S. fleet blimp squadrons plus an extensive training and experimental program at Lakehurst, war and postwar headquarters of naval lighter-than-air activity. The activation of a naval reserve airship training program was also planned. As part of Lakehurst experimentation to determine the sea-keeping and habitability features of airships, the 725,000 cu.ft. XM-1 (formerly the 647,500 cu.ft. M-1) on Nov. 2, 1946, established a 170 hr. 17 min. world's aircraft endurance record for continuous unrefuelled flight.

Civil airship activity was resumed in 1946 with the purchase and operation of surplus navy K- and L-type blimps for advertising purposes by the Goodyear company, Douglas Leigh Sky Advertising corporation and Hughes Aircraft corporation.

## AIRSHIP OPERATION AND CONSTRUCTION CONSIDERATIONS

This discussion is limited to the nonrigid airship and omits consideration of rigid activity because of its world-wide termination in 1940 with the dismantlement of the German Zeppelin LZ-130.

**Flight Principles.**—An airship or balloon floats in the air whenever the sum of the weight of the gas container (and any structural weights or other loads hanging therefrom) plus the weight of the very light lifting gas is the same as or less than the weight of the air which the airship or balloon displaces. This Archimedean precept is the fundamental principle of airship flight. Airships lighter than the air they displace experience a buoyant force tending to make them ascend; those which are heavier will tend to descend. The lift acquired by an airship from the buoyancy of its gas is known as static lift.

When a lighter-than-air craft is buoyant, it is in a "light" condition. When its weight and static lift are equal, it is "in equilibrium"; it is "heavy" when its weight exceeds its static lift. An airship is also subject to dynamic lift derived from its motion through the air. While its hull is by no means an efficient airfoil, its size produces an appreciable lifting effect when driven through the air at an inclination. The "heavy" airship utilizes this dynamic lift of the hull and fins as well as static lift and, like an aeroplane, becomes airborne by means of a take-off run on its landing gear. U.S. navy blimps have taken off as much as 6,000 lb. "heavy." "Light" airships are sufficiently buoyant to become airborne without a take-off run. While blimps which are "heavy" fly at a slight inclination to make use of the lifting effect of the air flow, "light" airships conversely fly slightly nose down, so that the air flow against the top side of the envelope will counteract the lightness and the constant static tendency to gain altitude The static condition of airships varies in flight, depending upon such factors as the amount of fuel consumed (each gallon of gasoline weighs six pounds) and changes in weather conditions. Extreme heaviness can be remedied by ballast expenditure while excessive lightness can be overcome by picking up sea water or other ballast and valving lifting gas.

Normal control of altitude is maintained neither by the expending of ballast nor by the valving of helium. To ascend, "up elevator" is given, raising the airship's elevators which are flippers attached to the horizontal fins. The air flow about the moving airship strikes these raised surfaces and depresses the tail, thus lifting the nose; the engines drive the ship upward. To descend, "down elevator" raises the tail and lowers the nose, enabling the motors to drive the ship earthward. Rudder control is similarly exerted; the air flow, striking the rudder surfaces (attached to the upper and lower vertical fins), turns the tail, hence the nose, in the desired horizontal direction. The control of an airship in many respects resembles that of a submarine, the blimp's elevators and rudders corresponding to the undersea craft's diving planes and rudder.

**Lifting Gases and Pressure Control.**—At sea level and at standard conditions, air weighs about 81 lb. per 1,000 cu.ft. There

are only a few gases which give any practical lift in air, the most commonly used being hydrogen, helium and coal gas. Because of the weight of coal gas, its use is restricted to free balloons of limited performance. Pure hydrogen and helium weigh 5 and 11 lb. per 1,000 cu.ft. respectively, and their corresponding lifts are 76 and 70 lb. However, impurities generally present reduce these values to working figures of 68 lb. for hydrogen and 62 lb. for helium. The disadvantage of the lesser lift of the helium is offset by the noninflammable nature of the gas, an advantage which caused the U.S. to adopt a "helium only" policy in airship operation. The higher cost of helium (approximately $15 per 1,000 cu.ft. as against about $6 for hydrogen) plus the fact that its shipment and storage are complicated and expensive make it necessary that helium valving practice be much more conservative than that used with hydrogen inflation. (*See* HELIUM.)

In nonrigid airships, internal gas pressure and its maintenance between maximum and minimum safety levels are vital. A blimp flying with low pressure reduces the firmness of its envelope and is endangered by the possibility that the air flow might cause the bag to fold or buckle. On the other hand, excessively high pressure places undue strain on the envelope, perhaps causing it to rip were it not for helium valves which automatically operate when the pressure exceeds the safety limit. This problem of maintaining proper pressure is aggravated by the eccentricities of gases which continually expand and contract because of temperature and altitude changes. To compensate for these changes in helium or hydrogen volume, nonrigid airship envelopes contain air compartments known as ballonets.

The 425,000 cu.ft. envelope of a K-ship (representative of standard airship design) consisted of one helium chamber and two ballonets. When the envelope was inflated with helium to its maximum capacity, the gas chamber contained 425,000 cu.ft. of helium and the air ballonets were empty. If during flight a decrease in temperature or altitude caused the 425,000 cu.ft. of helium to contract to 400,000 cu.ft., the operation of the ballonets ensured the maintenance of constant and adequate pressure. As the 25,000 cu.ft. of helium disappeared through contraction, an electric blower or the propeller slip stream blew an equivalent volume of air into the ballonets which inflated within the envelope, thereby replacing the missing helium and keeping the pressure constant. If the gas later expanded to a volume of 410,000 cu.ft., 10,000 cu.ft. of air were then released from the ballonets by automatic valves. The total capacity of the K-ship's two ballonets was 114,000 cu.ft.—slightly more than one-quarter of the total bag volume. By means of these air ballonets, K-ship helium pressure was maintained at a point equivalent to the weight of 1.5 in. of water. Ballonets, because of their fore and aft locations, may also be utilized for trimming purposes.

**Construction Details.**—A modern nonrigid airship envelope ordinarily consists of three layers of long staple cotton fabric impregnated with rubber. The envelope is divided into a system of gores and panels, the seams of which are lapped, cemented, sewed and taped to reduce gas leakage which is still further discouraged by coating the envelope's inner side with paraffin. An aluminum paint on the outer side reflects the sun and reduces the amount of heat absorption by the envelope, thereby helping to minimize the degree of helium expansion. Battens, which are fabric covered strips of wood laced to the envelope, reinforce and stiffen the blimp's nose to avert its buckling at high speeds.

The car or gondola in modern nonrigid airship practice is suspended against the bottom of the envelope by a system of internal and external catenary curtains. The internal catenaries, consisting of strong fabric mounted in parallel rows running fore and aft, hang down from the top inside the envelope. From these curtains suspension cables extend to the framework of the car. Another catenary curtain is located outside and at the bottom of the envelope; to this external suspension system, the top of the car is affixed.

Personnel, armament, power plants and virtually all the equipment of a nonrigid airship are carried by its car, which rests upon a wheel (sometimes retractable) to make possible wheel ("heavy") take-offs and landings. The power plants, usually aeroplane type gasoline engines, are mounted on outriggers extending from either side of the car; access to the engines is possible in flight. Because of their large size (42 ft. in length for the K-ship, 115 ft. for the M-ship), airship cars possess good habitability characteristics and are fitted with the finest communications and navigational equipment.

Each blimp is equipped with a number of ropes and lines used in ground handling operations to steady and hold the ship in position or to pull a "light" craft to earth.

At the extreme bow of the airship is a round disk mounting a horizontal spindle to which a cone is attached. The mooring of an airship is normally accomplished by fitting this cone into a cuplike device at the top of the mooring mast. With its nose held in this manner, an airship is docked, undocked or "walked" across the field by means of a mobile, tractor-towed, triangular-shaped, steel mast, in the case of a K-ship about 43 ft. high.

**Future Development.**—Although the U.S. navy's 725,000 cu.ft. XM-1 was at its time of building the largest successful nonrigid airship ever constructed, it by no means represented the maximum volume permissible with the nonrigid type of construction. Progress in the development of stronger and lighter envelope fabrics makes nonrigids exceeding 1,000,000 cu.ft. capacity entirely practicable. However, increased gas volume makes possible greater car loading; this increased weight, when concentrated in a short car, imposes considerable strain on the catenary curtains and envelope. Accordingly, modern airship practice calls for a proportionately longer car to provide a more equitable weight distribution on the bag. In the case of the XM-1, its 115-ft.-long car was built of three sections integrated by universal joints to provide a degree of flexibility.

With the development of improved power plants, it was considered in 1947 that a maximum air speed of about 90 to 100 m.p.h. was obtainable with standard established hull designs and propulsion methods. This figure, although low compared with aeroplane speeds, offers no great disadvantage to lighter-than-air development because the utility of the airship is derived not from its maximum speed but from its ability to conduct hovering or low speed, long endurance operations. One aspect of power plant improvement during World War II was the incorporation of electric reversible propellers to facilitate landing operations by slowing or stopping the forward motion of the ship so that it could be more readily taken in hand by the ground crew.

Under war demands, U.S. navy airships from 1942–45 operated daily under severe weather and climatic conditions, leading to the development of new operational techniques. For example, the landing of blimps in winds of 35 knots was in peacetime an emergency measure; in wartime operations, routine landings were made in these and in winds approaching 50 knots. The prewar notion that successful blimp operations necessitated expensive hangars and supporting bases was refuted in 1943 when K-ships began day and night operations from wooden stick masts at primitive isolated jungle bases with a minimum of equipment and personnel. During these South American operations, which were conducted a thousand miles or so from airship hangars, blimps were exposed to the rigours of the equatorial sun and the tropical rains. In so doing, they demonstrated their ability to operate in such fabric deteriorating conditions for months without other hangar availability than that necessary for routine overhaul or repair purposes. Of the 50-odd airship bases utilized by U.S. navy blimps during World War II, only 13 possessed hangar facilities. It was thought as experience was gained by continued operations, additional progress in operating and maintenance technique would follow. New developments in ground handling operations could additionally be expected as improved mechanical means were evolved for the landing, mooring, docking or undocking of airships with consequent reduction in ground crew personnel requirements.

The post-World War II employment of U.S. navy airships began with emphasis upon experimentation. Because of the large carrying capacity and the size of airship cars, the installation of heavy or bulky equipment is possible in airships which additionally are unusually stable airborne platforms. For this reason, air-

ships before and during World War II were used to pioneer, test and prove many aeronautical, scientific and technical advancements. Continuation of this activity in peacetime under the cognizance of the Lakehurst-based Naval Airship Training and Experimental command was authorized with promising prospects of improvements in airship antisubmarine, utility, mine spotting, and rescue devices and operating procedures.

**AIRSHIP SHEDS.** The term airship shed is used synonymously with airship hangar or airship dock to denote a building or other structure in which airships are housed for construction, storage, repair or overhaul purposes.

Sheds are not normally essential for operations since both rigid and pressure airships can be "moored out" and operate from masts for extended periods of time. Airships can be serviced and given minor repairs at masts, and being capable of operating from aircraft carriers and specially fitted airship tenders, require hangar availability only for major repairs and overhaul or for protection from severe weather conditions.

When airships were small, their sheds were of simple barnlike construction with wooden or fabric walls and with swinging doors. Earliest hangars were built on the water or sometimes mounted on turntables, so that they could be turned into the wind. The advent of larger airships, however, seriously complicated shed design. It became necessary to develop mammoth structures devoid of interior supports, yet so designed that neither the shed nor its doors would seriously disturb the normal air flow over the airport, thereby complicating the landing and manoeuvring of airships.

The world's largest airship shed, completed by the Goodyear Tire and Rubber company at Akron, O., in 1929, is an arch-shaped structure with orange-peel doors—a design inaugurated by Germany prior to World War I. The Akron dock required about 7,500 tons of structural steel and has a floor area of 364,000 sq.ft. and a cubical content of 45,000,000 cu.ft. At each end there are two spherical-calotte doors which can be opened electrically in five minutes; each door weighs 600 tons, the weight being taken by 40 wheels running on circular railroad tracks. These orange-peel doors rotate about hinge pins in the roof, so that in the fully opened position they nestle along the arched sides of the shed. A similar type hangar with slight modifications and smaller dimensions was constructed about 1933 by the U.S. navy at Sunnyvale (later renamed Moffett field), Calif.

The extensive U.S. navy nonrigid airship (blimp) program of World War II brought about the construction of numerous airship bases and sheds along the U.S. Atlantic, Gulf and Pacific coasts. Two 960-ft.-long, 330-ft.-wide, 200-ft.-high steel hangars of orange-peel door design were erected at South Weymouth Mass., and Weeksville, N.C. Other hangars were needed, and to conserve steel a new type shed of wooden construction with concrete foundations was designed and erected at South Weymouth (1); Weeksville (1); Lakehurst, N.J. (2); Glynco, Ga. (2); Richmond, Fla. (3); Houma, La. (1); Hitchcock, Tex. (1); Santa Ana, Calif. (2); Moffett Field, Calif. (2); and Tillamook, Ore (2). These 17 hangars were, with slight modifications, identical in size and design. The dimensions of the 2 Lakehurst wooden

| Exterior hangar width, max. | 297 " |
| Exterior hangar height, max. | 173 " |

sheds shown in the table in column one can therefore be taken as representative of the 15 others.

The wood which went into the construction of these sheds was chemically treated to make it fire resistant. Much of the structure was prefabricated; the truss joints of the wooden beams were bolted together. With the exception of the hangar at Houma, each shed mounts folding leaflike sectional doors which are 120 ft high supported on railroad rails at the top and bottom of the door sill. These doors fold away in recesses between twin reinforced concrete pylons on either side of the shed. The pylons support a box beam girder carrying the upper rail on which the electrically operated doors slide. The doors of the Houma structure are detachable and, when opened, move on railroad tracks off to one side completely apart from the shed. The three hangars at Richmond were totally destroyed by a hurricane and fire in Sept. 1945. Many of the world's most famous airship sheds, including those of the German Zeppelin company, were destroyed during World War II. The location and dimensions (in feet) of the larger sheds still remaining after the war, excluding the wartime U.S. navy steel and wooden hangars already described, are listed in the table. **AIR SICKNESS:** *see* ANOXAEMIA.

**AIR WARFARE.** Military aviation came into being when Louis Bleriot flew across the English channel from Calais, France to Dover, England, on July 25, 1909. Many military men never realized the significance of that flight. Some more farsighted experts, however, began to readjust their ideas as to the warfare of the future. Napoleon had looked longingly across the channel but could not take his army across. Engineers had talked for years about putting a tunnel under the channel but the British objected that it would remove their isolation. Then Bleriot in a few minutes completely removed the bars to British isolation from the continent of Europe. What one aeroplane could do, certainly hundreds and thousands could do.

There was little done to make the aeroplane a practical, effective military weapon between 1903 and 1914. Isolated tests and experiments indicated that the device was capable of doing more in warfare than merely carrying messages and observing for the ground troops. As early as the fall of 1911, the United States army corps had tried out Riley Scott's aerial bomb release. It was many years ahead of its time as it mathematically figured out the proper point from which to drop the bomb to hit a target. The war department was not interested so Scott took his device to France, entered the Michelin contests for accurate bombing and easily won first prize. He had no competition and his hitting

target 375 x 124 ft. with 8 out of 15 bombs dropped from an altitude of 2,624 ft. was far beyond the conception of accuracy for any of the airmen or military men in Europe. As a result they bought the device.

In the spring of 1912 Col. I. N. Lewis, of the U.S. army, introduced a new type of machine gun. The type which was then in use was impractical in that it had a long feed slide which made the operation of the aeroplane controls impossible. However, the decision made in the war department was that the old Benet Mercier machine gun was standard for the army and would be standard for the aeroplanes. Lewis, following the precedent established by Scott, went to Europe for the sale of his gun.

These were two very important events in the history of military aviation. Two years later in 1914 World War I broke out in Europe. The Scott ideas had been incorporated into bombsight developments by that time, and the Lewis guns were installed as permanent equipment on some types of planes in European flying units. The small air corps of the world powers, however, went into World War I in Aug. 1914 still untried.

## WORLD WAR I

At the beginning of World War I, aircraft production had not as yet become a technique of jigs, dies, fixtures and special fittings. Each and every aeroplane was a handmade task. No country, not even France, supposed to be far more air-minded than any other nation, had available 400 combat planes in Aug. 1914.

The ideas of the general staffs were clear with regard to how they were going to employ their cavalry, artillery, infantry and their navies, but the aeroplane was still an unknown quantity. All agreed that it had great possibilities as a reconnaissance vehicle. It could go behind the enemy lines and locate troops, concentrations of reserves moving along the roads, and it might even find them in bivouac, even in woods. What else could the aeroplane be used for?

The air enthusiasts were sure that it could be used in combat against other planes, that it could be used to carry bombs and destroy predesignated targets, but how? So it was that World War I became one of the best proving grounds to develop the aeroplane as a combat weapon.

**Armament.**—The Lewis gun had been used on military aircraft but only for rear-seat firing. A fighter plane must have fire power from the front. The normal technique of air operations indicated that most aerial attacks should be made in that way. There was one major problem to be solved: how could a machine gun be fired through the propeller without hitting and destroying it?

There were numerous solutions suggested for this problem. At first the airmen flew past each other shooting such weapons as they might have in their hands—pistols, shotguns, rifles or machine guns. All those methods of solving the problem were far from satisfactory, as they seldom made hits. The next step was to mount a machine gun on top of the upper wing of a biplane so that it fired over the propeller. A sight mounted along the top of the fuselage made it possible for the gunner to get accurate aim, but the mounting was very unwieldy. It was hard to fix jams in the air and it was difficult to change drums of ammunition.

Next came the razor sharp steel pieces mounted at the rear of the propeller in the line of fire of a gun located in the fuselage. The bullets either went through the blades as they rotated or they hit the steel knife blades. If they hit the knife blades, no harm was done. The big step forward came when Anthony H. G. Fokker, a Dutch aeroplane designer working for the Germans in the fall of 1915, brought out the first synchronizing gear. This gear made it possible for the gun to be fired at will by the pilot through the propeller with no ill effects; the gun was so synchronized with the moving propeller that no bullet could hit the propeller blades. That device put Germany well ahead of the Allies insofar as fighter planes were concerned.

**Bombing.**—The bombing efforts went through the same cut-and-try procedure before a satisfactory bombsight, type of bomb or technique of operation was secured. The first bombs dropped were round hollow shells. The bombardier ignited the fuse by scratching a prepared plug in the bomb against a prepared surface along the sides of the aeroplane. If the fuse caught and he judged his timing right, the round shell might explode somewhere near the target.

The next step was to put fins on artillery shells and use them. About the same time some French airman conceived the idea of employing fluted darts, pointed at one end. It was figured that if enough of the darts were dropped, some of them might hit marching enemy soldiers on the head and penetrate in spite of the steel helmets. Such bombing technique was, to say the least, ineffective and inefficient.

The first bombsights were of simple construction and operation. All of the World War I planes had open cockpits, and the bombsight was mounted on the side of the fuselage. The bombardier bent his head over the side of the cockpit, made his adjustments and then pulled the trigger. The bomb release apparatus was created to eliminate the human error of dropping the bombs by hand and to prevent complicating the planes with attachment gear when large sized bombs were used. As the war progressed bomb release gear became standardized and could be attached to any type of plane.

**Formation Flying.**—The mission alone could not determine the trend in aeroplane design. Both the Germans and the Allies were out to shoot down as many hostile aircraft as they could either from the air or from the ground. So it became necessary to bring out formations which gave the most protection against hostile air attacks and provided the least vulnerable target against hostile anti-aircraft gunfire. Strange as it may seem, it was the synchronizing gear of Fokker's that caused the Allied flying units to seek better protection. They were unable to get it through fire power on one plane, hence they brought several planes together so that a heavy volume of fire could be secured from the mass. Thus in the fall of 1915 the Allied airmen used the first "V" formations for mutual protection. While the formations at first were small in size, the numbers involved in a single formation grew until at the end of the war it was not unusual to see as many as 50 or 60 planes employed in a single formation by both the Germans and the Allies.

**Types of Planes.**—Combat brought out standardized types of planes although there were almost as many models as there were manufacturers.

*Fighter.*—The fighter was a sturdy, compact and rugged plane with the highest horsepower possible and the best possible speed and climb. Through all the years which followed, the characteristics of that type of plane, jet or orthodox, did not change. High-speed races with their large prizes provided incentive each year for better racing planes and provided the testing ground of future fighter planes.

*Observation Plane.*—As most of the higher ranking officers in the war saw observation work as the primary mission of the aeroplane, a large percentage of the total planes available was assigned to such tasks. Ground troops needed to know the location of the enemy in front of them and whether or not there were fieldworks, trenches or barbed wire. Early in the war the aerial observers demonstrated that they could perform such observation duties well. In addition they took photographs which showed exact details of the terrain, even paths made by new troops moving into concealed positions.

The observation plane flew unescorted. It went through the stages of a two-seater, three-seater, heavily armed with machine guns, lightly armed. It was fixed with bomb racks and soon became a general purpose plane which could be used for observation, light bombing or as a two-seater fighter. It was seldom that the pilot of an observation plane was able to rely on support from fighting planes. Normally he went in to enemy territory to get information by himself and fought his way out against enemy fighter planes and anti-aircraft artillery.

*Bomber.*—When the United States entered the war in April 1917, the status of the various types of planes was about as outlined above. Large bombs indicated the necessity for large bombing planes. However, when it was decided to start

quantity production of aeroplanes, it was indeed a problem to determine which planes should be built. There were numerous models. Even the British, French, Belgians and the Italians could not agree among themselves as to which they should recommend. The problem of engine design was equally complex. The United States decided to build its own engine, the Liberty, which could be used as a general purpose engine in observation planes, day bombers and the two-seater fighters.

At that time the Germans were far ahead in the field of bomber development. They were using night bombing against targets in England and in western France. Their heavy bombers were comparatively slow, about 90 m.p.h. as compared with the fighter's 120 m.p.h., but they could carry bomb loads of about 1,000 lb. for several hundred miles.

In the bomber class England had the Handley Page, with two engines, and Italy the Caproni with three. U.S. military leaders had already selected the de Havilland as an observation general purpose plane and had decided that the U.S. would not build any fighter planes. The difficult decision lay in selecting the type of bomber to be built. It was finally agreed that both the Handley Page and the Caproni were to be produced in the United States. Production matters, however, were further complicated by the introduction of Glenn L. Martin's two-engined bomber in 1918. A number of these planes were also built in the last days of the war.

In view of the precedent set by the aircraft industry in its tremendous output of training planes for the British, Canadian and U.S. air forces, little difficulty was anticipated in producing the bomber. It became apparent, however, that there were many unforeseen problems connected with the construction of this type of plane, for when World War I ended in 1918, the United States had produced about 4,500 DH-4s of which about 1,216 had reached France. Shipments of Handley Pages were too few in number to be of any value in the course of the hostilities.

**Tactics of Aerial Combat.**—As the number of aeroplanes increased on the European front and as armament became more powerful, it became evident that the day of individual aerial combat was over. So came the development of aerial tactics.

*The Squadron.*—The smallest administrative organization practically universally accepted for air units was the squadron. There the men were fed, their planes were repaired and maintained, sleeping accommodations were provided and the records of all men were kept. The squadron varied in size from 50 to 250, depending upon whether it was a fighter, observation or bomber squadron. It was also the smallest tactical fighting unit. Although all types of manoeuvres were utilized, the time finally came when it was obvious that the squadron must receive support in combat. There was not enough flexibility in that one organization to secure the best results. Additional squadrons seemed to be the answer.

*The Group.*—The group, made up of two, three or four squadrons, was a natural division not only for command in the observation and bomber units but also in the combat operations of the fighters. In the fighters, it was a cardinal principle to get above the opponent. When one squadron fought independently, if a flight of three planes acted as a decoy there were but two flights of three planes left to attack. With the group formation, entire squadrons could come into the combat to swing the tide of battle as necessary.

The French and the U.S. organized squadrons into groups. The British organized them into wings.

*The Wing.*—In actual practice in warfare, there was not much use for the term wing, made up of two or more groups, until Gen. William Mitchell, of the U.S., assembled about 1,500 planes for the St. Mihiel offensive in 1918. This was the largest fleet of aeroplanes ever assembled up to that time, and it was not until World War II that the figure was reached again.

The U.S. ground forces had assembled more than 500,000 men for that offensive. Mitchell planned to isolate the battlefield to deny the Germans reinforcements in men or supplies. He hit the Germans on one flank and then the other with formations of 500 planes. Then he attacked them in the rear areas where supplies and reinforcements were being brought up. It was the first employment of aeroplanes in mass.

**Changing Techniques of Combat (1916–1918).**—The hit-or-miss methods first employed in aerial combat did not last long. The Fokker plane at first gave Germany the advantage, and it was the Allies who sought safety in numbers. Then in the summer of 1916, the Allied offensive patrols began. Planes flying in "V" formations sought out the enemy. When fairly large numbers of these "V's" were used, the Germans were no match even with their better performing planes. For the first time the Allies had attained superiority in the air.

The Germans tried to regain air superiority early in 1917 by bringing out new planes with two guns firing through the propeller instead of one. In addition they had superior performance. The technique of operations was unchanged but the pendulum swung once more to the German side until by the spring of 1917 their superiority was practically unchallenged. By the summer of 1917, however, the British and French had brought out new types of fighters and once more air superiority went to the Allies.

**Tactics of Attack.**—The simplest form of air tactics in World War I was for one fighter to creep up on a slower plane from the rear, in the area of the latter's blind spot, and shoot it down. Every variation from that simple manoeuvre complicated matters. If the attack was made from an angle, the pilot had to figure his speed, the speed of his opponent, the distance between the planes and the wind direction and velocity. Under certain conditions the consideration of all these things in the sighting formula might make the pilot aim to the rear of the hostile pilot and engine in order to get a hit.

By getting above his opponent, the fighter pilot could then, by superior speed, select his own point of attack. Accordingly fighter pilots, whether operating in flight units, in squadrons or in groups, always tried to get above their opponents. The old two seater type of plane and the slow bomber did not present much of a problem to the fighter.

## MILITARY AVIATION, 1918–1939

The period following World War I was used by practically all nations to determine the practical value of the aeroplane. The war had brought out the fact that although it was faster than any other means of travel and could be used for destroying other planes and for securing information for the ground forces as a weapon of destruction its value was extremely limited. In the United States, Gen. William Mitchell had long contended that air power was superior to sea power. In 1921 he conducted bombing tests on captured German warships. A submarine, destroyer, cruiser and battleship were bombed and sunk with a few well-placed 1,000-lb. bombs. In later tests, held in 1923, Mitchell's bombers, flying at 10,000 ft., sank the old battleships "Virginia" and "New Jersey" with 2,000-lb. bombs. The bomber had become a part of the air team.

During the period when Mitchell directed the operations of the U.S. army air corps, a flight was made from Mineola, L.I., N.Y., to Alaska and back under command of Capt. St. Clair Street in July 1920. Other outstanding flights showed the capabilities of modern aircraft. The first refuelling flight was conducted by Lieut. L. H. Smith and Lieut. J. P. Richter at Rockwell field, Calif., in Aug. 1923. Successive transatlantic flights showed that the ocean had ceased to be a military barrier to large planes. On May 2–3, 1923, Lieut. Oakley Kelly and Lieut. John Macready flew the T-2, a plane built by Anthony Fokker, former German plane manufacturer, nonstop from New York to San Diego, Calif. Although equipped with a single Liberty engine, it could carry a useful load of 3,000 pounds in addition to about eight men.

The U.S. navy kept pace with the army improvements in military planes. In the early days of flying the navy took the normal aeroplane and equipped it with floats. Then the flying boat came into the picture in 1916. The hulls were so heavy that for a while, at least, the flying boat was not very efficient. However the impetus of World War I brought out the NC type.

Naval planes followed the course of the army planes in development and construction only with the more complicated problem

tacked by 1,500 heavy bombers with eight groups of fighter bombers bombing and strafing the area for 15 min. before the heavies' attack that lasted for an hour, and with seven groups of fighter bombers going over the area from low level for 30 min. afterward. Immediately following that attack, all the light and medium bombers of the 9th bomber command wound up the operation with both area and pin-point attacks.

The U.S. infantry advanced and breached the enemy positions west of St. Lô, and freed Gen. George Patton's armour to push deeper into German-held territory. The enemy did not stand successfully again until France and Belgium had been liberated and the west wall reached.

Once Patton's 3rd army was out in the open his armoured divisions always had an escort of fighter bombers. When the 1st army joined the 3rd army near Argentan and trapped about 57,000 Germans, the 11th tactical air command of the 9th air force came in to hasten the surrender. In one day the 11th T.A.C. destroyed from 400 to 500 enemy vehicles.

**The Italian Campaign.**—In Italy the Allied air forces' efforts to assist the progress of the ground forces were successful, but not so spectacularly so as they were in France. In spite of their best efforts, the Allies were unable to stop completely the flow of essential supplies to the Germans in Italy. Nevertheless, when the ground positions in Italy stabilized following the Anzio landing in Jan. 1944, and an attempted flanking assault failed, it was thought that air attack could diminish the enemy's ability to supply, reinforce and shift his forces, and would thus so weaken him that he could neither withstand determined ground attack nor withdraw in good order.

Medium and fighter bombers attacked key bridges on the few rail lines from northern Italy to the front. From March 24 to the fall of Rome on June 4 two principal choke lines were maintained across the narrow boot. No through trains were able to run from the Po valley to the front lines, and south of Florence nearly all supplies had to be moved by truck. The enemy attempted to increase the use of shipping, but heavy bombers attacked the vessels. The Germans diverted trucks to hauling supplies around the broken bridges and, eventually, all the way from Florence to Rimini, but fighter strafing forced the trucks to operate only at night.

Germany's ability to transport supplies was reduced from an estimated 80,000 tons a day to not more than 4,000. When the Allied drive began in early May, the enemy's transport was unable to meet the demands on it. The German lines broke under the impact of the ground offensive. Retreat in good order was impossible because of the breakdown of transportation under the constant air attack.

**Industrial Collapse in Germany.**—Once Allied troops were securely established in France the campaign against the German chemical industry began in strength. By the end of 1944 the output of aviation gasoline was cut 90%, and from December on, German war production ran downhill rapidly. A month later railroad carloadings were off 75% and steel was being produced at only 20% of capacity. The strategic air war was practically over. In March the chief of German armament production, Albert Speer, knew that the third reich was finished. "The German economy," he reported, "is heading for inevitable collapse within 4–8 weeks." After Germany's surrender on May 8, Allied interrogators asked Speer if he believed strategic bombardment alone could have won the war. Speer replied: "Yes, the attacks on the chemical industry alone [synthetic oil] would have sufficed without the impact of purely military events."

## WAR IN THE PACIFIC

In making its decisive contribution to the victory in Europe the U.S. air force alone dropped a far greater tonnage of bombs than it dropped during the war in the Pacific. The Japanese were defeated before the U.S. bombing effort reached its peak. From 1943 onward, the United States enjoyed air superiority in the Pacific, and exploited it so thoroughly that World War II ended with the unconditional surrender of Japan while its armies, which had never been defeated in large scale fighting, held nearly 3,000,000 sq.mi. of southeastern Asia and dominated the lives of 500,000,000 people.

The collapse of Japan vindicated the whole strategic concept of the offensive phase of the Pacific war. In the simplest terms, that strategy called for the advance of air power, both land based and carrier based, step by step to the point where it could bring destructive power to bear directly on the Japanese homeland. When such a point was reached it was a certainty that air power would make invasion of the Japanese home islands possible. As it turned out, air power and sea power were so effective in combination that no invasion was necessary.

**Allied Air Offensive.**—On Jan. 24, 1942, the 10th air force began operations from around Chungking, in Yunnan province, China. Its first combat unit, the 23rd fighter group, had been organized from the American Volunteer group—the famous Flying Tigers. The job of the 10th at that time was to knock out Japanese airports and shoot down enemy planes, dive-bombing gunboats, junks and barges. When B-25s came to the 10th in the summer of 1942 they went after enemy shipping, docks, air bases, supply depots and troop concentrations.

In New Guinea the 5th air force was carrying out much the same sort of an operation. A year after Pearl Harbor the 5th was equipped with 81 heavy bombers, 83 medium bombers and 238 fighters. With this small force the 5th performed miracles, working out solutions to the problems posed by long overwater flying, high mountains, extensive jungle and bad weather.

In the summer of 1942, following the remarkable U.S. naval victory at Midway where four Japanese carriers were sunk, three battleships were damaged, a heavy cruiser was sunk and a number of lighter vessels were sunk or damaged, U.S. troops on Guadalcanal and Tulagi were getting air support from the 13th air force based on Espiritu Santo. At the other end of the Pacific the 11th air force had more to fight than the Japanese. In Alaska and the Aleutians, where it was based, the weather was a constant and implacable enemy. Lubricating oil congealed, tires froze to the ground; rain, snow and fog followed each other in rapid succession. Instrument flying was the usual practice in an area where mountains rose to great heights, and islands rose straight from the surface of the sea like mountain peaks. Dutch Harbor, in the Aleutians, was attacked by Japanese bombers on June 3, 1942. Air force and navy flyers had found a Japanese task force less than an hour's flying to the southeast, with two carriers, two cruisers and eight destroyers. In spite of the fact that the weather reduced visibility nearly to zero U.S. aircraft sank one of the cruisers and damaged another. Less than two weeks later aerial photographs showed Japanese on Attu, Agattu and Kiska. Their installations were bombed continually by the 11th during the next 11 months, and when U.S. surface forces finally drove them off, they didn't realize they had accomplished their mission until aerial photographs, interpreted in the United States, showed that the Japanese positions had been abandoned.

By June 1943 the tide was beginning to turn in the Pacific. On Feb. 9, 1943, Guadalcanal had fallen to U.S. forces, and on March 1–4, in the Bismarck sea action, the 5th air force and the Royal Australian air force had virtually wiped out a large Japanese convoy and its supplies, as well as nearly a division of troops, proceeding from Rabaul to Lae.

The primary objective of the Allied forces in the southwest Pacific was to advance a network of air bases deep into the Japanese perimeter. On June 30, Allied land, sea and air forces moved against the Japanese in the Solomons-New Guinea area in a simultaneous, three-pointed assault, and U.S. forces occupied Rendova Island in New Georgia. On Sept. 13 Salamaua fell to the Allies, and three days later Lae, which the Japanese had held since Jan. 1942, was recaptured. Meanwhile, the 5th air force carried out heavy attacks on Wewak and prepared Salamaua for recapture by hitting it, on July 27, with one of the heaviest bomb loads ever dropped in the southwest Pacific up to that time.

On Sept. 18–20, 1943, units of the 7th air force and two navy carrier task forces attacked Tarawa, Makin, Apamama and Nauru. The following week the 5th air force returned to Wewak, and as October began, a naval task force including six aircraft carriers

bombed Wake Island, dropping 320 tons of bombs and causing serious damage. With resistance in the central Solomons ended, the 5th air force began a series of devastating attacks on the great Japanese naval base at Rabaul on Oct. 12 that were to continue on into November.

The Japanese perimeter fell inward again when U.S. troops landed on Makin Island without opposition on Nov. 20, and simultaneously more U.S. troops established themselves successfully on Tarawa in a bloody action. In preparation for both of these attacks B-24s of the 7th air force bombed defense positions.

**The B-29 Superfortress.**—Meanwhile the plans division of air force headquarters in Washington, D.C., was giving a great deal of thought to how a new air weapon, to be available for operational use sometime in June 1944, should be employed. The new weapon was the B-29 which had been on the drawing boards in 1939. Germany was not considered as a B-29 target because the B-17s and B-24s in England would be hitting their full stride at the time the B-29s would be ready, and had all the range they needed to finish the task even though their bomb capacity was far less. On the other hand, Japan itself would remain free from bombardment for a long time unless the B-29s got into operation against it.

China was an obvious place to base the new Superfortresses, but there were no suitable airports closer than Chengtu or Chungking. The Marianas—specifically Guam, Tinian and Saipan—were selected as bases for up to 1,000 B-29s. Unfortunately, despite excellent progress in the Pacific, the Allies were a long way from the Marianas at the beginning of 1944. Hence, it was decided to get the Superfortresses into action from Chinese bases despite the difficulties of supply and the distance to Japan—2,000 mi. from Chengtu to Tokyo as compared to 1,400 or 1,500 mi. from the Marianas.

The first B-29 bombing attack occurred on June 5, 1944. Bangkok was the target and in order to hit it, the B-29s had to carry their own gasoline and bombs 1,200 mi. from Assam to Chengtu. On June 15 they hit the steel mills at Yawata and Japan was under direct, sustained attack for the first time in the war. Sasebo, Anshan, Palembang, Nagasaki and Yawata were repeatedly attacked from Chinese bases. All this, however, gave only a hint of what was to come when the Superfortresses began to operate from the Marianas.

**Invasion of the Marshalls and Marianas.**—On Feb. 7, 1944, the Japanese perimeter was again dented, this time in the Marshall Islands with the occupation of Kwajalein and Majuro. By Feb. 19, Eniwetok, westernmost of the Marshalls, had also been captured after light enemy resistance. Once on Eniwetok, U.S. forces found themselves about 2,400 mi. farther west of Pearl Harbor than they had been four months before. The Japanese inner defenses were exposed.

The question was simply where to strike next. The decision was influenced by the growing availability of B-29s and the need for bases to support further advances into the Palaus, the Philippines, Formosa and China. The joint chiefs of staff decided to by-pass Truk and strike at the southern Marianas. Truk was to be on the receiving end of a long series of neutralizing air attacks. The target date for the occupation of the Marianas was set as June 15, 1944.

Right on schedule, Saipan was attacked. During the seven days preceding the attack, heavy bombers of the 7th and 13th air forces had hit Truk to neutralize its threat to the landing operation. By July 9, organized resistance on Saipan had ended, and ten days later Guam was attacked. While the troops were moving steadily forward on Guam, Tinian was attacked on July 24. By Aug. 8 Tinian and Guam were in Allied hands.

On Nov. 24, 1944, the first B-29 mission took off from the Marianas. On that date, 100 Superfortresses left Saipan and bombed Tokyo for the first time since Gen. James Doolittle, on April 18, 1942, had taken off from the deck of the carrier "Hornet" and led 16 B-25s against Tokyo, Nagoya, Kobe and Yokohama. Within a month the B-29s had hit Tokyo three more times. They followed these attacks with one on Nagoya where they virtually demolished the Mitsubishi aircraft plant.

As 1945 began the 20th air force had a total of 345 B-29s on Guam, Tinian and Saipan and a total of 51,800 officers and men. In the five weeks of 1944 in which they had operated they had destroyed 254 Japanese aircraft and dropped 9,000 bombs.

**Bombing of Japan.**—In March 1945 Gen. Curtis LeMay, commanding officer of the 20th air force, made one of the important decisions of the war—to attack Tokyo with incendiaries at low level at night with his full force. Never before had the B-29s bombed from altitudes of less than 24,000 ft., but on the night of March 9, Tokyo was attacked by 279 B-29s at a mean bombing altitude of 7,050 ft. The Japanese defenses were confused, and only 14 B-29s were lost from all causes. About 15.8 sq.mi. of the heart of Tokyo were burned out in what was, prior to the use of atomic bombs on Aug. 5 and 8, the most destructive air attack in history. The Tokyo attack was followed by devastating night incendiary attacks on Nagoya, Kobe and Osaka in quick succession.

By the war's end, the incendiary attacks had dropped 100,000 tons of bombs in the course of 15,000 sorties against 66 Japanese cities. The United States strategic bombing survey, after an exhaustive on-the-spot study of industrial facilities following V-J day, found that aerial bombardment had cut the Japanese productive capacity, as compared to its preattack output, tremendously. Oil refineries suffered a cut of 83%; aircraft engine plants, 75%; airframes, 60%; electronics and communication, 70%; army ordnance plants, 30%; naval ordnance plants, 28%; merchant and naval shipyards, 15%; light metals, 35%; ingot steel, 15%; and chemicals, 10%.

Coupled with the decisive strategic bombing of Japan was the blockade of the home islands. Since early in the war the Japanese merchant fleet had been a primary target of Allied sea, air, and submarine forces. To the submarines of the U.S. navy goes the chief credit for reducing the Japanese merchant fleet to the point where, on V-J day, that fleet consisted of about 300 ships—a little more than 1,000,000 gross tons, or 20% of the shipping afloat when the war began. In addition, aircraft sank more than 1,000,000 tons of shipping in 1944, and despite the growing scarcity of targets continued this rate until the end of the war, when the sea-air blockade was, to all intents and purposes, complete.

The B-29s made a major contribution to this achievement. One wing of the 20th air force was trained in aerial mining operations, and during the four days prior to D-day on Okinawa dropped more than 1,000 tons of mines in the Shimonoseki straits, closing the Inland sea to all large vessels for ten days to two weeks.

(H. H. Ar.; X.)

**AIRWAY,** an artery of a mine, along which the ventilation is conducted. The districts branching from the fresh air "intakes" are ventilated by "splits" taken off the main airway. The current conducted along the branch or district intakes, round the "working face," returns by the district "return airway," enters the main "return airway" and proceeds thence to the upcast shaft up which it is drawn to the surface by fans. This is the practice in coal mining in Great Britain. In France the ventilation is generally carried out by compression, that is by fans forcing the air down the "downcast" shaft and through the workings to the "upcast."

The position, number and arrangement of the airways in an ideal coal mine are shown in the figure overleaf, as well as the manner in which the air is split for district ventilation. (*See* also Coal and Coal Mining.) *See* diagram overleaf. (R. R.)

**AIRY, SIR GEORGE BIDDELL** (1801–1892), British astronomer royal, was born at Alnwick on July 27, 1801. He was educated at Colchester grammar school and at Trinity college, Cambridge, where he graduated as senior wrangler in 1823. He became a fellow of his college (1824), Lucasian professor of mathematics (1826), and then (1828) Plumian professor of astronomy and director of the new Cambridge observatory. Before long a mural circle was installed, and regular observations were instituted with it in 1833. In the same year the duke of Northumberland presented the Cambridge observatory with a fine object-glass of 12 in. aperture, which was mounted according to Airy's designs and under his superintendence, although the erection was not completed until after his removal to Greenwich in 1835. Airy's writings during this time are divided between mathematical physics and astronomy. The former were for the most part concerned

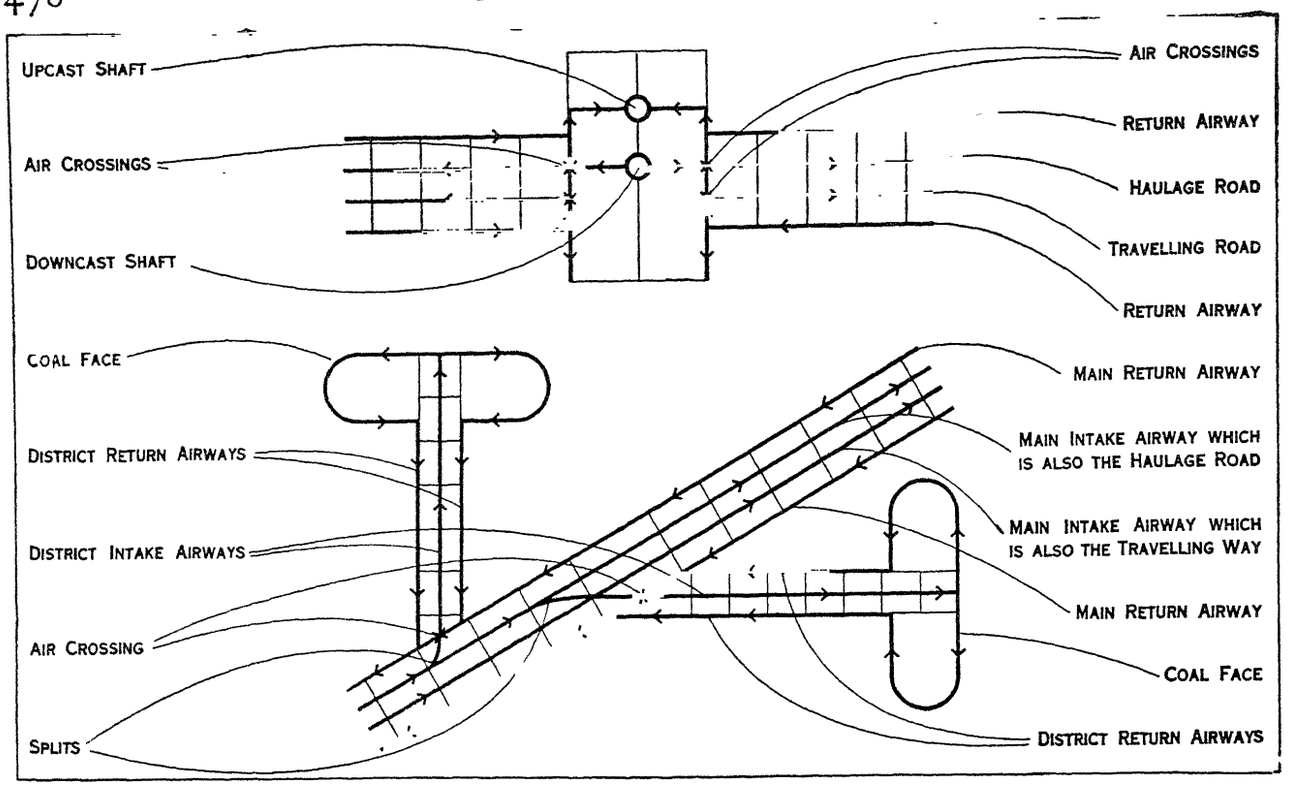

DIAGRAM ILLUSTRATING THE INSTALLATION OF AIRWAYS AND VENTILATING CURRENTS IN MINES—(SEE PAGE 477)

The upper plan shows the shaft pillars and the position of the main airways in the neighbourhood. The lower plan shows the main and district airways. The arrows in both plans indicate the direction of inward and outward air currents which make up the system of ventilation below ground

with questions relating to the theory of light, arising out of his professorial lectures, among which may be specially mentioned his paper "On the Diffraction of an Object-Glass with Circular Aperture." Of his astronomical writings during this period the most important are his investigation of the mass of Jupiter, his report to the British Association on the progress of astronomy during the 19th century, and his memoir *On an Inequality of Long Period in the Motions of the Earth and Venus.*

Airy's discovery of a new inequality in the motions of Venus and the earth was a remarkable achievement. In correcting the elements of Delambre's solar tables he discovered an inequality overlooked by their constructor. Eight times the mean motion of Venus is so nearly equal to 13 times that of the earth that the difference amounts to only the $\frac{1}{240}$th of the earth's mean motion, and from the fact that the term depending on this difference, although very small in itself, receives in the integration of the differential equations a multiplier of about 2,200,000, Airy was led to infer the existence of a sensible inequality extending over 240 years (*Phil. Trans.*, cxxii. 67). The investigation leading to this result was probably the most laborious that had been made up to Airy's time in planetary theory, and represented the first specific improvement in the solar tables effected in England since the establishment of the theory of gravitation.

In June, 1835, Airy was appointed astronomer royal in succession to John Pond. Under Airy's administration modern apparatus was installed, and the whole organization placed on a scientific footing. No fewer than 8,000 lunar observations were rescued from oblivion, and were, in 1846, placed at the disposal of astronomers in such a form that they could be used directly for comparison with the theory and for the improvement of the tables of the moon's motion. (*See* HANSEN, PETER ANDREAS.)

One of the most remarkable of Airy's researches was his determination of the mean density of the earth. In 1826 the idea occurred to him of attacking this problem by means of pendulum experiments at the top and bottom of a deep mine. After some failures, successful experiments were made at the Harton pit, near South Shields, in 1854. Their immediate result was to show that gravity at the bottom of the mine exceeded that at the top by $\frac{1}{19,286}$th of its amount, the depth being 1,256ft. From this Airy was led to the final value of 6·566 for the mean density of the earth as compared with that of water (*Phil. Trans.* cxlvi. 342). At the age of 71 Airy embarked on a new method of treating lunar theory. A general description of his method will be found in the *Monthly Notices of the Royal Astronomical Society,* Vol. xxxiv. No. 3. It consisted essentially in the adoption of Delauny's final numerical expressions for longitude, latitude and parallax, with a symbolic term attached to each number, the value of which was to be determined by substitution in the equations of motion. The work was published in 1886, when its author was 85 years of age. In 1881 Sir George Airy resigned the office of astronomer royal and resided at the White house, Greenwich, not far from the Royal observatory, until his death, which took place on Jan. 2, 1892. The learned societies of his own and other countries conferred many honours on him.

BIBLIOGRAPHY.—A list of Airy's papers will be found in his *Autobiography,* edited in 1896 by his son, Wilfrid Airy, B.A., M. Inst. C.E. *See* also his *Mathematical Tracts* (1826) *on the Lunar Theory, Figure of the Earth, Precession and Nutation,* and *Calculus of Variations,* to which, in the second edition (of 1828), were added tracts on the Planetary Theory and the Undulatory Theory of Light; *Experiments on Iron-built Ships, instituted for the purpose of discovering a correction for the deviation of the Compass produced by the Iron of the Ships* (1839); *On the Theoretical Explanation of an apparent new Polarity in Light* (1840); *Tides and Waves* (1842).

**AISLABIE, JOHN** (1670–1742), English politician, born Dec. 7, 1670. He was made chancellor of the Exchequer in 1718, and supported the proposal of the South Sea Company to pay off the national debt. At the collapse of the company he was imprisoned in the Tower with other politicians accused of attempting to profit fraudulently from the scheme, but was soon released, through Walpole's intervention.

**AISLE,** in architecture, a term primarily meaning the wing of a house, but more commonly used to indicate any long, narrow space separated from the remainder of the building by a line of piers, columns or arches. It is specially used to designate the lateral portions of a church or other large room in which interior supports occur. The term also has come to mean a passageway,

specially a passageway between groups of seats, as in a church or theatre. From the time of the early Christian basilica, the use of one or more side aisles flanking a central nave has been almost universal in church building, and church aisles are known as nave aisles, transept aisles or choir aisles from their position in relation to the nave, transept or choir. The choir aisle around the east end of a choir is known as an ambulatory (*q.v.*). In the normal Romanesque or Gothic church the roof of the aisles is lower than the central nave; but in certain examples in southern France (*e.g.*, St. Nazaire, Carcassonne), in Spain (*e.g.*, Barcelona), and especially in Germany, where for the smaller churches it is almost normal, the nave and aisles are of the same height. A church with nave flanked by one aisle on each side is known as a three-aisle church; one with two side aisles on each side as a five-aisle church, and so on.

**AISNE,** department, northern France, west of Ardennes (*q.v.*). Area 2,868 sq.mi. Pop. (1946) 453,411. It touches the western end of the Ardennes (930 ft.) in the northeast, but its surface is all of secondary or tertiary rocks. The outlying masses of the latter, often with steep flanks, form important sites such as that of Laon, the capital, and the famous Chemin des Dames. The Aisne enters the department from the east just as it leaves the chalk scarp and flows west to the Oise, the other river of the department. It has been made to stretch down to include the deep Château-Thierry portion of the Marne valley, too far west to focus on Épernay or Reims and allied to the hill country farther north rather than to Paris on the west. The department was the scene of much of World War I. It had a number of forests, but it lacks metallic ores, though quarries yield building stone, gypsum and clay. Mostly in the belt of rainfall 600–800 mm., and well watered and sheltered, it has had great farming prosperity, with specialization in dairying towards the northeast. Of the towns, Guise in the north does agricultural and other engineering and St. Quentin and numerous villages do weaving of cotton, wool and silk. St. Gobain has made mirrors since the 17th century. Sugar has been an important crop and industry. Communications are good by rail and by navigable rivers (Aisne, Oise, Marne). St. Quentin, Vervins, Laon and Soissons give their names to arrondissements and are, with Château-Thierry and Hirson (*qq.v.*), the chief towns. This department and that of Oise were rich in architectural monuments several of which were ruined in World War I, but the churches at Laon, Braine and Urcel (mainly 12th century) survived and the splendid *Basilique* of St. Quentin was largely repaired, while the castle-ruin (1400) of La Ferté-Milon did not suffer. Soissons is the seat of a bishop in the province of Reims, the court of appeal is that of Amiens (Somme), also the centre of the 2nd army corps. The department belongs to the educational province (*académie*) of Douai.

**Aisne, Battle of the, 1918.**—This title is one of several alternatives used to designate the third great German offensive of 1918, launched on May 27, against the Chemin des Dames ridge and rapidly carried across the Aisne and southward to the Marne. It is described under CHEMIN-DES-DAMES, BATTLE OF THE, 1918.

**AÏSSÉ** (a corruption of HAÏDÉE), MADEMOISELLE (*c.* 1694–1733), French letter-writer, was the daughter of a Circassian chief, and was born about 1694. Her father's palace was pillaged by the Turks, and as a child of four years old she was sold to the comte de Ferriol, the French ambassador at Constantinople. She was brought up in Paris by Ferriol's sister-in-law with her own sons, MM. D'Argental and Pont de Veyle. Her great beauty and romantic history made her the fashion, and she attracted the notice of the regent, Philip, duke of Orleans, whose offers she had the strength of mind to refuse. She formed a deep and lasting attachment to the Chevalier d'Aydie, by whom she had a daughter. She died in Paris on March 13, 1733. Her letters to her friend Madame Calandrini contain much interesting information with regard to contemporary celebrities, especially on Mme. du Deffand and Mme. de Tencin, but they are above all of interest in the picture they afford of the writer's own tenderness and fidelity.

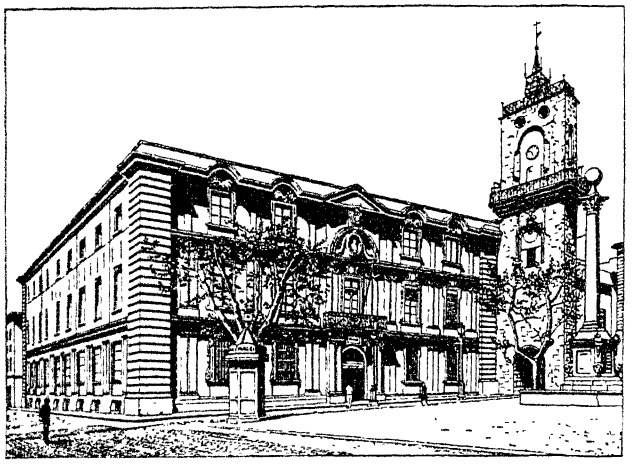
Her *Lettres* were edited by Voltaire (1787), by J. Ravenel, with a notice by Sainte-Beuve (1846) and by Eugène Asse (1873). Mlle. Aïssé has been the subject of three plays: by A. de Lavergne and P. Foucher (1854), by Louis Bouilhet (1872) and by Dejoux (1898). *See* also Courteault, *Une Idylle au XVIIIe siècle, Mlle. Aïssé et le Chevalier d'Aydie* (Mâcon, 1900). There is an interesting essay by Sir E. Gosse in his *French Profiles* (1905).

**AISTULF** (d. 756), king of the Lombards (749–56). His first act as king was to drive the Greeks from the exarchate of Ravenna and to occupy the city, thus placing his army within striking distance of Rome. Pope Stephen II was forced to appeal to Pepin, king of the Franks, to defend the city, and in the campaigns of 755 and 756 Aistulf was defeated. The future of both the papacy and of the Lombard kingdom rested on Pepin's victory. The papacy was saved from becoming merely subordinate to the Lombard rule, and the Lombards were eventually (774) conquered by the Franks, who remained permanently hostile.

**AITKEN, ROBERT GRANT** (1864–1951), U.S. astronomer, was born in Jackson, Calif., on Dec. 31, 1864. Aitken was educated at Williams college, Williamstown, Mass., from which he graduated in 1887 and received his M.A. in 1892. In 1888–91 he was instructor of mathematics in Livermore college, and 1891–95 was professor of mathematics and astronomy in the University of the Pacific. In 1895 he was appointed astronomer at Lick observatory, Mt. Hamilton, Calif., of which he was director 1930–35. Here he specialized in the study of double stars, of which he discovered more than 3,000. For these discoveries, he was awarded in 1906 the Lalande prize by the Academy of Sciences of France and, in 1932, the gold medal of the Royal Astronomiçal society. He published *Binary Stars* (1918) and *New General Catalogue of Double Stars* (1932). He died Oct. 29, 1951.

**AITON, WILLIAM** (1731–93), Scottish botanist, was born near Hamilton in 1731, and died on Feb. 2, 1793. As director of Kew Gardens (1759–93) he effected many improvements, and in 1789 he published *Hortus Kewensis,* a catalogue of the plants there cultivated. A second and enlarged edition of the *Hortus* was brought out in 1810–13 by his eldest son, WILLIAM TOWNSEND AITON (1766–1849), who succeeded him at Kew.

**AITZEMA, LIEUWE (LEO) VAN** (1600–1669), Dutch historian and statesman, was born at Doccum, in Friesland, Nov. 19, 1600, and died at The Hague, Feb. 23, 1669. His most important work was the *Saken van Staet in Oorlogh in ende omtrent de Vereenigt Nederlanden* (1655–71), embracing the period from 1621 to 1668. It contains a large number of state documents, and is an invaluable authority on one of the most eventful periods of Dutch history. Four continuations of the history, by the poet and historian Lambert van den Bos, were published. The *Derde Vervolg Zijnde het vierde Stuck van het Vervolgh op de Historie,* etc., brought the history down to 1697.



**AIVALI,** Turkey: *see* AYVALIK.

**AIX,** city of southeast France, capital of an arrondissement in the department of Bouches-du-Rhône, 18 mi. N. of Marseille. Pop. (1946) 46,053. It is situated in a plain overlooking the Arc, about a mile from the right bank of the river. Aix (*Aquae Sextiae*) was founded in 123 B.C., by the Roman consul Sextius Calvinus. In 102 B.C. Marius defeated the Cimbri and Teutones there. In the 4th century it was the metropolis of Narbonensis Secunda. Occupied by Visigoths in 477, and repeatedly plundered by Franks and Lombards, it was taken by Saracens in 731. During the middle ages it was the capital of the county of Provence and reached its zenith after the 12th century, when the houses of Aragon and Anjou made it an artistic centre and seat of learning. It passed with Provence to the crown in 1487, and had the parlement of Provence (1501–1789). In the 17th and 18th centuries it was the seat of the *intendance* of Provence.

The Cours Mirabeau divides the town into the new town to the south and the old town to the north. Aix is the seat of the faculties of law and letters of the University of Aix-Marseille. The cathedral of St. Sauveur dates from the 11th, 12th and 13th centuries. It has a rich Gothic portal with elaborately carved doors. The archbishop's palace and a Romanesque cloister adjoin the cathedral on its south side. The church of St. Jean de Malte (13th century), contains valuable pictures. The *hôtel de ville* (17th century) contains fine wood-work and a large library

with valuable mss. Aix has thermal springs, remarkable for their heat and containing lime and carbonic acid; baths have been built (1705) near the site of the Roman baths. The industries include flour-milling, the making of confectionery, the manufacture of hats and the preparation of olive-oil. Trade is in olive-oil, almonds and flour.

The town, which is the seat of an archbishop and court of appeal and the centre of an *académie,* has a court of assizes, tribunal of commerce, and a chamber of arts and manufactures. It also has museums of antiquities, natural history and painting, and several learned societies.

THE SQUARE IN AIX SHOWING THE COURT HOUSE AND CLOCK TOWER

**Aix, Battle of** (Aquae Sextiae).—After the Roman disaster at Arausio (*q.v.*) in 105 B.C. the great migration of the Cimbri and Teutones turned aside to Spain, thus enabling Marius (*q.v.*) to gain breathing space to organize and train his "new model" army. But in 102 B.C., returning to Gaul, these tribes moved to invade Italy, the Cimbri going round the north of the Alpine barrier and the Teutones by the Mediterranean coast. On their approach Marius entrenched himself and refused to be drawn out to battle, content to repulse their assault and to acclimatize his men to the sight and ways of their strange and terrifying foe. When the host passed onwards, Marius cautiously followed until on reaching Aquae Sextiae, now Aix, 20m. N. of Marseille, a partial engagement was brought on by the common desire to gain possession of the only available water supply. The Romans were successful and after a two days' pause, Marius judged the moment ripe for battle, having detached a force of 3,000 men to take up a concealed position on the enemy's flank. His cavalry and light infantry were then used to draw out the Teutones to attack, which Marius awaited on the slope of a hill. This first onslaught was stopped with difficulty, but gradually the Romans pressed their assailants downhill. Before the Teutones could reform on the level, they were struck in rear by the flank detachment, and their very numbers then intensified the press and their difficulty. The disaster was so complete that not merely the menace but the tribe itself was dispersed.

**AIX-LA-CHAPELLE:** *see* AACHEN.

**AIX-LA-CHAPELLE, CONGRESSES OF.** Three congresses have met at Aix-la-Chapelle—in 1668, in 1748 and in 1818.

1. The treaty of May 2, 1668, which ended the War of Devolution, was the outcome of that of St. Germain signed on April 15 by France and the representatives of the Triple Alliance. The Treaty of Aix-la-Chapelle left to France all the conquests made in Flanders during 1667, with all their *"appartenances, dépendances et annexes,"* a vague provision of which, after the peace of Nimwegen (1680), Louis XIV. took advantage to occupy villages and towns adjudged to him by his *Chambres de réunion* as dependencies of the cities and territories acquired in 1668. On the other hand, France restored to Spain Cambrai, Aire and Saint-Omer, as well as Franche Comté. The Treaty of Aix-la-Chapelle was placed under the guarantee of Great Britain, Sweden and Holland, by a convention signed at The Hague on May 7, 1669, to which Spain acceded.

*See* Jean du Mont, baron de Carlscroon, *Corps universel diplomatique* (Amsterdam, 1726–31).

2. On April 24, 1748, a congress assembled at Aix-la-Chapelle to end the War of Austrian Succession. The definitive treaty was signed on Oct. 18. Its most important provisions were those stipulating for (1) a general restitution of conquests, including Cape Breton to France, Madras to England and the barrier towns to the Dutch; (2) the assignment to Don Philip of the duchies of Parma, Piacenza and Guastalla; (3) the restoration of the duke of Modena and the republic of Genoa to their former positions; (4) the renewal in favour of Great Britain of the Asiento contract of March 16, 1713, and of the right to send an annual vessel to the Spanish colonies; (5) the renewal of the article of the treaty of 1718 recognizing the Protestant succession in the English throne; (6) the recognition of the emperor Francis and the confirmation of the pragmatic sanction, *i.e.,* of the right of Maria Theresa to the Hapsburg succession; (7) the guarantee to Prussia of the duchy of Silesia and the county of Glatz.

Spain having raised objections to the Asiento clauses, the Treaty of Aix-la-Chapelle was supplemented by that of Madrid (Oct. 5, 1750), by which Great Britain surrendered her claims for a sum of £100,000.

*See* Comte G. de Garden, *Hist. des traités de paix,* iii. p. 373 (1848–87).

3. The congress or conference of Aix-la-Chapelle in 1818 was primarily a meeting of the four Allied Powers—Great Britain, Austria, Prussia and Russia—to decide the question of the withdrawal of the army of occupation from France and the consequent international relationships of the Powers. The congress, which opened on Oct. 1, was attended by Alexander I. of Russia, Francis I. of Austria, and Frederick William III. of Prussia, in person. Great Britain was represented by Lord Castlereagh and the duke of Wellington, Austria by Prince Metternich, Russia by Counts Capo d'Istria and Nesselrode, Prussia by Prince Hardenberg and Count Bernstorff. The duc de Richelieu, by favour of the allies, was present on behalf of France. The evacuation of France was agreed to in principle at the first session, the consequent treaty being signed on Oct. 9. The rest of the time of the congress was mainly occupied in discussing the form to be taken by the European alliance, and the precautions to be adopted against a fresh outburst on the part of France. The proposal of Alexander I., to establish a "universal union of guarantee" on the broad basis of the Holy Alliance, broke down on the opposition of Great Britain; and the main outcome of the congress was the signature, on Nov. 15, of two instruments: (1) a secret protocol confirming and renewing the Quadruple Alliance established by the treaties of Chaumont and Paris (Nov. 20, 1815) against France; (2) a public "declaration" of the intention of the Powers to maintain their intimate union, of which the object was to preserve peace on the basis of respect for treaties. The secret protocol was communicated in confidence to Richelieu; to the declaration France was invited publicly to adhere.

The congress also concerned itself with the questions of the suppression of the slave trade and the Barbary pirates. In neither case was any decision arrived at, owing (1) to the refusal of the other Powers to agree with the British proposal for a reciprocal right of search on the high seas; (2) to the objection of Great Britain to international action, which would have involved the presence of a Russian squadron in the Mediterranean. A great variety of lesser questions was considered, but an attempt to introduce the subject of the Spanish colonies was defeated by the opposition of Great Britain. The congress represents the highest point reached in the attempt to govern Europe by an international committee of the Powers.

(W. A. P.)

**AIX-LES-BAINS,** thermal spa and fashionable resort, east France, in the department of Savoie, near the Lac du Bourget, 9 mi. by rail N. of Chambéry. Pop. (1936) 8,917. The sulphur springs were known as *Aquae Gratianae* by the Ro[illegible]

neighbourhood has numerous ancient remains. Over 50,000 visitors are ordinarily attracted annually; the main season is July–September, but Aix also serves as a base for Alpine winter sports.

**AIYAR, SIR SHESHADRI** (1845–1901), Indian statesman, the son of a Brahman of Palghat, Malabar, rose from a humble position as translator in his native district to be prime minister of Mysore under the Maharaja Chamarajendra. To him Mysore owes many important public works and the development of the Kolar gold-fields. Aiyar retired in 1900 and died on Sept. 13, 1901.

**AIYAR, SIR TIRUVARUR MUTUSWAMY** (1832–1895), native Indian judge of the high court of Madras, was born of poor parents in the village of Vuchuwadi, near Tanjore, on Jan. 28, 1832. His widowed mother was forced by poverty to remove with Mutuswamy and his brother to Tiruvarar, where the former learnt Tamil, and soon set to work under the village accountant at a monthly salary of one rupee. Aiyar worked his way through a series of minor offices until he was able to take his degree in law. He then became a judge of the Madras small causes court, and in 1878 he was raised to the bench of the high court, which office he occupied with ability and distinction for over fifteen years, sometimes acting as the chief justice. He attended by invitation of the viceroy the imperial assemblage at Delhi in 1877. In 1878 he received the honour of C.I.E. and in 1893 the K.C.I.E. was conferred on him. He died suddenly in 1895. Aiyar took his full share in the affairs of the Madras university, of which he was nominated a fellow in 1872 and a syndic in 1877, and was well acquainted with English law, literature and philosophy. He was through life a staunch Brahman, devout and amiable in character, with a taste for the ancient music of India and the study of the Vedas and other departments of Sanskrit literature.

**AJACCIO,** capital of Corsica, on the west coast of the island. Pop. (1936) 34,393. Ajaccio occupies a sheltered position at the foot of wooded hills on the north shore of the Gulf of Ajaccio. The harbour, to the east, is protected on the south by a peninsula which carries the citadel. It is deep enough to shelter large ships. To the southwest of the peninsula lies the Place Bonaparte, frequented by winter visitors attracted by the mild climate. Apart from one or two fine thoroughfares, the streets are narrow. The present town of Ajaccio lies about 2 mi. south of its original site, from which it was transferred by the Genoese in 1492. Occupied in 1553 by the French, it again fell to the Genoese after the treaty of Cateau Cambrésis in 1559. The town finally passed to the French in 1768. Since 1810 it has been the capital of the department of Corsica. The associations of Napoleon I with the town are everywhere emphasized by street-names and statues. The town is the seat of a bishopric (7th century) and of a prefect. It has tribunals of first instance and of commerce and a museum. Ajaccio makes cigars and macaroni and carries on shipbuilding, sardine-fishing and coral-fishing. Its exports include timber, oranges, citrons and skins.

**AJAIGARH,** an Indian state in the Central India states. It has an area of 788 sq.mi., and a population in 1941 of 96,596. The ruler, who is a Bundela Rajput, bears the title of sawai maharaja and has a salute of eleven guns. He resides at Ajaigarh, at the foot of the hill-fortress from which the state takes its name. This fort is situated on a very steep hill, more than 800 ft. above the town, and contains the ruins of temples with elaborate sculptures.

**AJANTA** (more properly Ājūnthā), a village in the dominions of the Nizam of Hyderabad in India, celebrated for its cave hermitages and halls, in a wooded and rugged ravine about 3½m. from the village. The ravine is that of the river Wâgura which falls from the east over a bluff forming several waterfalls. The caves, about 30 in number, are excavated in the south side of the precipitous bank of the ravine, and are of two kinds—dwelling-halls and meeting-halls. The former have a broad verandah, its roof supported by pillars, and giving towards the interior on to a hall averaging in size about 35ft. by 20ft. Dormitories are excavated opening on to this hall, and an image of the Buddha usually stands in a niche facing the entrance. In the larger caves pillars support the roof on all three sides, forming a sort of cloister running round the hall. The meeting-halls which back into the roel-about twice as far as the dwelling-halls, were used as chapteio houses for the meetings of the Buddhist Order. The oldest caves date from 200 B.C. to A.D. 200, the next belong approximately to the 6th, and the youngest to the 7th century A.D. Most of the interior walls of the caves are covered with fresco paintings, of considerable merit, and somewhat in the early Italian style. When first discovered, in 1817, these frescoes were in a fair state of preservation, but they fell later into decay. The remains are now properly preserved, and form, with copies of those destroyed, important evidence as to pre-Hindu art in India. Ajanta was a kind of college monastery.

**AJAX** (I.) *the Greater* Gr. Aἴας, son of Telamon, king of Salamis. In Homer's *Iliad* he is described as of great stature and colossal frame, second only to Achilles in strength and bravery. He engaged Hector in single combat and, with the aid of Athene, rescued the body of Achilles from the hands of the Trojans. In the competition between him and Odysseus for the armour of Achilles, Agamemnon, at the instigation of Athene, awarded the prize to Odysseus. This so enraged Ajax that it caused his death (*Odyssey,* xi. 541). According to a later and more definite story, accepted by Sophocles as the basis of his drama, his disappointment drove him mad; he rushed out of his tent and fell upon the flocks of sheep in the camp under the impression that they were the Greeks; on coming to his senses he slew himself with the sword which he had received as a present from Hector. From his blood sprang a red flower (*see* HYACINTHUS) which bore on its leaves the initial letters of his name AI, also expressive of lament (Pausanias i. 35. 4.). He was the tutelary hero of the island of Salamis, where he had a temple and an image, and where a festival called *Aianteia* was celebrated in his honour (Pausanias i. 35).

II., *the Lesser,* son of Oïleus, king of Locris, called the "lesser" or Locrian Ajax, to distinguish him from the son of Telamon. In spite of his small stature, he held his own amongst the other heroes before Troy; he was brave, next to Achilles in swiftness of foot, and famous for throwing the spear. But he was boastful, arrogant, and quarrelsome. Athena wrecked his ship on his homeward voyage (*Odyssey,* iv. 499), presumably for his crime (not definitely mentioned by Homer) in dragging Cassandra from the statue of the goddess, during the sack of Troy, and violating her. This led to the thousand years' penance of his people; nevertheless, he was worshipped as a national hero by the Opuntian Locrians (on whose coins he appeared), who always left a vacant place for him in their battle line.

**AJMERE** or **AJMER,** a city of India in Rajputana, which gives its name to a district and also to a petty province called Ajmere-Merwara. Pop. of the city (1941) 147,258. It is on the lower slopes of Taragarh Hill, in the Aravalli mountains. To the north of the city is a large artificial lake called the Ana Sagar, and farther up the valley is a new lake, the Foy Sagar, from which the water supply of the place is now derived.

The chief object of interest is the *darga,* or tomb of the famous Mohammedan saint Muin-ud-din Chishti. It is situated at the foot of the Taragarh hill, and consists of a block of white marble buildings without much pretension to architectural beauty. To this place the emperor Akbar, with his empress, performed a pilgrimage on foot from Agra in accordance with the terms of a vow he had made when praying for a son. An ancient Jain temple converted about A.D. 1200 into a mosque, is situated on the lower slope of the Taragarh hill. With the exception of that part used as a mosque, nearly the whole of the ancient temple has fallen into ruins, but the relics are not excelled in beauty of architecture and sculpture by any remains of Hindu art. Forty columns support the roof, but no two are alike, and great fertility of invention is manifested in the execution of the ornaments. The summit of Taragarh hill, overhanging Ajmere, is crowned by a fort, the lofty thick battlements of which run along its brow and enclose the tableland. The walls are 2m. in circumference, and the fort can only be approached by steep and very roughly paved planes,

the fort and the outworks, and by the hill to the was founded about the year A.D. 145 by Ajaipal, a established the dynasty which continued to rule the with many vicissitudes of fortune) while the repeated of Mohammedan invasion swept over India, until it eventu- became an appanage of the crown of Delhi in 1193. Its internal government, however, was handed over to its ancient rulers upon the payment of a heavy tribute to the conquerors. It then remained feudatory to Delhi till 1365, when it was captured by the ruler of Mewar. Akbar took it back in 1556; and it continued in the hands of the Moguls, with occasional revolts, till 1770, when it was ceded to the Mahrattas, from which time up to 1818 the unhappy district was the scene of a continual struggle, being seized at different times by the Mewar and Marwar rajas, from whom it was so often retaken by the Mahrattas. In 1818 the latter ceded it to the British in return for a payment of 50,000 rupees.

The modern city is an important administrative and railway centre. It is well laid out with wide streets and handsome houses. The city does an active trade in salt which is imported in large quantities from the Sambar lake and Ramsur. Oil making is also a profitable branch of trade. Cotton cloths are manufactured to some extent, for the dyeing of which the city has attained a high reputation. The educational institutions include the Mayo Rajkumar college, opened in 1875, for training the sons of the nobles of Rajputana, on the lines of an English public school.

Seven miles from Ajmere lies the lake of Pushkar, one of the most sacred pieces of water in India, where a pilgrim fair is held every autumn, and Brahma has the only temple dedicated to him in India.

The district of Ajmere, which forms the largest part of the province of Ajmere-Merwara, has an area of 2,125 sq.mi. Population 378,960, inclusive of Ajmere city. Besides the city of Ajmere, the district contains the military station of Nasirabad, with a population of 32,196 (1941).

**AJMERE-MERWARA,** a former British district of India, in Rajputana agency, consisting of the two districts of Ajmere and Merwara, separated from each other and isolated amid Indian states. Pop. (1941) 583,693. The administration was in the hands of a commissioner, subordinate to the governor general's agent for Rajputana. The capital is Ajmere city. The area is 2,400 sq.mi. The Aravalli range is the distinguishing feature of the district. The range of hills which runs between Ajmere and Nasirabad marks the watershed of the subcontinent of India. The rain which falls on one side drains into the Chambal, and so into the Bay of Bengal; that which falls on the other side, into the Luni, which discharges itself into the Runn of Cutch. The province is on the border of what may be called the arid zone; it is the debatable land between the northeastern and southwestern monsoons, and beyond the influence of either. The southwest monsoon sweeps up the Nerbudda valley from Bombay and crossing the tableland at Neemuch gives copious supplies to Malwa, Jhalawar and Kotah and the countries which lie in the course of the Chambal river; but it is only when the monsoon is in considerable force that Merwara gets a plentiful supply from it. The northeastern monsoon sweeps up the valley of the Ganges from the Bay of Bengal and waters the northern part of Rajputana, but hardly penetrates farther west than the longitude of Ajmere. The agriculturist in Ajmere-Merwara can thus rarely rely upon two good harvests in succession. A district subject to such conditions can hardly be free from famine or scarcity for any length of time, but the population, having declined in the period from 1891–1921, showed a steady increase after 1921. Among Hindus, the Rajputs are landholders, and the Jats and Gujars are cultivators. The Jains are traders and moneylenders. The aboriginal tribe of Mers are divided between Hindus and Mohammedans. The chief crops are millet, wheat, cotton and oil seeds. There are several factories for ginning and pressing cotton, the chief trading centres being Beawar and Kekri.

**AJO,** an unincorporated town in Pima county, southern Arizona, U.S., about 25 mi. from the Mexican border and 90 mi. southwest of Phoenix; the altitude is 1,859 ft. It is on state highway 85 and is served by the Tucson, Cornelia and Gila Bend railroad. The population was 5,777 by the federal census of 1950. There are copper, gold, silver and lead mines in Ajo, and copper is smelted there. Spaniards were working the copper mines at Ajo as early as 1750. In 1854 the Ajo Copper company became the first incorporated mining company in the territory. After mining, the ore was hauled across the desert and shipped via the Gulf of California to Swansea, Wales, for smelting.

Originally, the town was called Muy Vavi, a Papago Indian term for warm water, but later it was changed to Ajo, Spanish for garlic, which grows plentifully in the nearby hills.

**AJODHYA,** an ancient city of India, situated on the right bank of the Gogra, in the Fyzabad district of the United Provinces. In remote antiquity Ajodhya was one of the largest and most magnificent of Indian cities. It is said to have covered an area of 96 sq.mi., and was the capital of the kingdom of Kosala, the court of the great king Dasaratha, who was the father of Rama, the hero of the *Ramayana.* The opening passages of that epic recount the magnificence of the city, the glories of the monarch and the virtues, wealth and loyalty of his people. A period of Buddhist supremacy followed the death of the last king of the Solar dynasty. On the revival of Brahmanism, Ajodhya was restored by King Vikramaditya (*c.* 57 B.C.). Kosala has claims to be the birthplace of the founders of both Buddhism and Jainism. The Chinese traveller, Hsüan Tsang, in the 7th century, found 20 Buddhist temples with 3,000 monks at Ajodhya, among a large Brahmanical population. The ancient city is now represented by a heap of ruins, with a few fine temples, and the modern town is only a small suburb of Fyzabad.

**AKA HILLS,** a tract of country on the northeast frontier of India, occupied by an independent tribe called the Akas. It lies north of the Darrang district of eastern Bengal and Assam, and is bounded on the east by the Dafla Hills and on the west by independent Bhutia tribes. The Aka country is very difficult of access, the direct road from the plains leading along the precipitous channel of the Bhareli river, which divides the Aka from the Dafla country.

The Akas are a brave people, and the men are strong and well made. They have clans graded socially, a dual organization and burial of the dead. They worship the Bhareli river annually, poison their arrows with aconite and play both varieties of nose flute.

The reputation of the Akas as raiders is sufficiently shown in the division of the tribe into two clans, the Hazari-khoas or "eaters of a thousand hearths," and the Kapah-chors or "thieves that lurk in the cotton fields." In the early years of British occupation, about 1829, they gave much trouble; and in 1883 they broke out once more into their old habits. They raided into the British district of Darrang and carried off several native forest officers as hostages. An expedition was sent against them under Gen. Sale Hill with 860 troops, which was completely successful. Living among them as a labouring but not servile class is the Niggiya or Khoa tribe divided into four clans.

*See* Nevill, "The Akas," *Assam Census Report,* 1921, I, App. B, i.

**AKALKOT,** a native state of India, in the Deccan and Kolhapur agency. It forms part of the Deccan tableland, and has a cool climate. Area 473 sq.mi.; pop. (1931) 92,605; (1941) 103,903. The tribute is £1,000. The state was under British management.

The town of Akalkot is situated near the Great Indian peninsula railway, which traverses the state. Pop. (1941) 13,810.

**AKAN,** a Gold Coast tribe inhabiting the Koforidua district of the Accra hinterland, neighbours of the Fanti and Ashanti, with whom they probably share a common origin, their language being closely related to these two idioms, and their organization being the same.

*See* Sarbah, *Fanti Customary Law* (1904).

**AKBAR, JALAL UD-DIN MOHAMMED** (1542–1605), the greatest of the Mogul (Mughal) emperors of India, was born at Umarkot in Sind when his father Humayun, who had been driven from the throne of Delhi by an Afghan usurper named Sher Shah, was escaping to Persia. Thirteen years passed before Humayun felt strong enough to attempt the reconquest of Hindustan,

and little had been accomplished before his death in 1556: in fact there was no Mogul empire before Akbar, but only the attempt to create one. Akbar's first task on his succession to the throne was to overthrow all rival claimants, the chief of them being the usurping Hindu minister Hemu whose forces were routed at Panipat on Nov. 5, 1556. By 1562 Akbar's kingdom embraced the Punjab and Multan; the basin of the Ganges and Jumna from Panipat to Allahabad, Gwalior in central India, Ajmere in Rajputana and the province of Kabul in Afghanistan. Another 14 years of almost incessant warfare resulted in the conquest of Malwa, Chitor, Ranthambhor, Kalinjar, Gujarat and Bengal. Thus, by 1576, Akbar was master of almost the whole of northern India. Between 1586 and 1595 he added Kashmir, Sind, Baluchistan, Kandahar and parts of Orissa to his dominions. With his power firmly established in the north he crossed the Narbada into the Deccan and annexed Khandesh, Berar and parts of Ahmednagar. At his death in 1605 his empire comprised 15 *subas* (provinces) and stretched from the Hindu Kush to the Godavari and from Bengal to Gujarat.

Akbar was endowed with a genius for administration to which the structure of both his central and provincial governments bears testimony. He deliberately accepted compromise as the basis of his empire and by his policy of *sulh-i-kull* (universal toleration) sought to conciliate the subject Hindu population and secure their loyalty. Realizing that it was impossible to govern as a strictly orthodox Moslem monarch, he abolished the hated *jizya* or poll-tax on non-Moslems and the tax previously levied on Hindu pilgrims. Hindus, especially Rajputs, were given important posts in the army and in the revenue department. To relieve the pressure on the peasants he demanded no more than one-third of their gross produce as land revenue. But although his interest in religious toleration was genuine his policy appears to have been dictated rather by political and dynastic considerations: his conception of sovereignty was autocratic and his religious policy an assertion of the supremacy of the state, politically, economically and financially. For this reason he crushed the power of the *ulema*, a body of orthodox divines and doctors of the law who constituted a check upon his power, by forcing them to subscribe to a document known as the Infallibility decree which assigned to Akbar the rank of *mujtahid* (interpreter) thus making him the authority on all matters relating to Islam.

Although illiterate Akbar was extremely interested in the study of comparative religion and built an *ibadat khana* or "house of worship" where learned men of all religions discussed theological problems. As a result of these discussions he became convinced that there was good in all religions and went so far as to promulgate a new eclectic faith called the *Din Illahi*. At his request three separate Jesuit missions were sent to his court; but they failed to convert him to Christianity as he was unable to give up the pleasures of the harem or subscribe to the doctrines of the Trinity and the Incarnation. The departure of his successors from the main principles of his rule, especially their policy of religious intolerance, paved the way for the decline of the Mogul empire.

**AKCHA,** a town and khanate of Afghan Turkistan, 42 mi. W. of Balkh on the road to Andkhui. It is protected by a mud wall and a citadel. Estimated population 8,000, chiefly Uzbegs. The khanate is small, but well watered and populous. The rivers which rise in the southern mountains end near Akcha in vast swamps filled in flood time with débris of hillside plants.

**AKEE,** the West African name of a small tree (*Blighia sapida*) of the soapberry family (Sapindaceae), native to Guinea, and also of its important food fruit. Introduced in 1778 into Jamaica, which now exports the fruit, its cultivation has spread throughout most of tropical America. The shrublike, stiff-branched tree, sometimes 20 ft. to 30 ft. high, bears handsome red or orange coloured fruits, about 3 in. long, in small clusters at the tips of slender branches. The fruit, which is a soft-walled capsule, splits when ripe into three sections, from apex to base, displaying round, shining, black seeds, attached to the base by large whitish or yellowish fleshy arils. When cooked the arils bear a resemblance to a fine omelette both in taste and in appearance; the Latin-American name *seso vegetal* (vegetable brain) is significant of their form.

**AKEN,** a town of Germany on the Elbe in the south-east of the district of Magdeburg, Prussian Saxony. Pop. (1939) 12,490. Chemicals and oils are manufactured. There is considerable transit trade on the Elbe, and petrol storage.

**AKENSIDE, MARK** (1721–1770), English poet and physician, was born at Newcastle-on-Tyne. He was the son of a butcher, and was slightly lame all his life from a wound he received as a child from his father's cleaver. He was sent (1739) to Edinburgh to study theology with a view to becoming a minister, but in fact studied medicine, and seems to have drifted to a mild deism. His politics, says Dr. Johnson, were characterized by an "impetuous eagerness to subvert and confound, with very little care what shall be established," and he is caricatured in the republican doctor of Smollett's *Peregrine Pickle*. He was elected a member of the Medical Society of Edinburgh in 1740. His ambitions already lay outside his profession, and his gifts as a speaker made him hope one day to enter parliament. In 1740 he printed his "Ode on the Winter Solstice" in a small volume of poems. In 1741 he left Edinburgh for Newcastle and began to call himself a surgeon, though it is doubtful whether he practised, and from the next year dates his life-long friendship with Jeremiah Dyson (1722–1776). During a visit to Morpeth in 1738 he had conceived the idea of his didactic poem, *The Pleasures of the Imagination*. He had already acquired a considerable literary reputation when he came to London about the end of 1743, and offered the work to Dodsley for £120. Dodsley thought the price exhorbitant, and only accepted the terms after submitting the manuscript to Pope, who assured him that this was "no everyday writer." The three books of this poem appeared in Jan. 1744. It was translated eventually into German, French and Italian, and gained a general success. His aim, Akenside tells us in the preface, was "not so much to give formal precepts, or enter into the way of direct argumentation, as, by exhibiting the most engaging prospects of nature, to enlarge and harmonize the imagination, and by that means insensibly dispose the minds of men to a similar taste and habit of thinking in religion, morals and civil life." Akenside's powers fell short of this lofty design; his imagination was not brilliant enough to surmount the difficulties inherent in a poem dealing so largely with abstractions; but the work was well received by the general public. His success was not unchallenged. Gray wrote to Thomas Wharton that it was "above the middling," but "often obscure and unintelligible and too much infected with the Hutchinson jargon." The reference was to Francis Hutcheson (1694–1746), author of an *Inquiry into the Original of our Ideas of Beauty and Virtue* (1725).

Into a note added by Akenside to the passage in the third book dealing with ridicule, William Warburton chose to read a reflection on himself. Accordingly he attacked the author of the *Pleasures of the Imagination*—which was published anonymously—in a scathing preface to his *Remarks on Several Occasional Reflections, in answer to Dr Middleton* . . . (1744). This was answered, nominally by Dyson, in *An Epistle to the Rev. Mr Warburton*, in which Akenside no doubt had a hand. It was in the press when he left England in 1744 to secure a medical degree at Leyden. In little more than a month he had completed the necessary dissertation, *De ortu et incremento foetus humani*, and received his diploma. Returning to England he attempted without success to establish a practice in Northampton. In 1744 he published his *Epistle to Curio*, attacking William Pulteney (afterward earl of Bath) for having abandoned his liberal principles to become a supporter of the government, and in the next year he produced a small volume of *Odes on Several Subjects*, in the preface to which he lays claim to correctness and a careful study of the best models. His friend Dyson had meanwhile left the bar, and had become, by purchase, clerk to the house of commons. Akenside had come to London and was trying to make a practice at Hampstead. Dyson took a house there, and did all he could to further his friend's interest in the neighbourhood. But Akenside's arrogance and pedantry frus-

trated these efforts, and Dyson then took a house for him in Bloomsbury Square, making him independent of his profession by an allowance stated to have been £300 a year, but probably greater, for it was asserted that his income enabled him to "keep a chariot," and to live "incomparably well." In 1746 he wrote his much-praised "Hymn to the Naiads," and he also became a contributor to Dodsley's *Museum, or Literary and Historical Register.*

He was now 25 years old, and began to devote himself almost exclusively to his profession. He was an acute and learned physician. He was admitted M.D. at Cambridge in 1753, fellow of the Royal College of Physicians in 1754, and fourth censor in 1755. In June 1755 he read the Gulstonian lectures before the college, in Sept. 1756 the Croonian lectures and in 1759 the Harveian oration. In Jan. 1759 he was appointed assistant physician, and two months later principal physician to Christ's hospital, but he was charged with harsh treatment of the poorer patients, and his unsympathetic character prevented the success to which his undeniable learning and ability entitled him. At the accession of George III, both Dyson and Akenside changed their political opinions, and Akenside's conversion to Tory principles was rewarded by the appointment of physician to the queen. Dyson became secretary to the treasury, lord of the treasury, and in 1774 privy councillor and cofferer to the household.

Akenside died on June 23, 1770, at his house in Burlington street, where the last ten years of his life had been spent. His friendship with Dyson puts his character in the most amiable light. Writing to his friend so early as 1744, Akenside said that the intimacy had "the force of an additional conscience, of a new principle of religion," and there seems to have been no break in their affection. He left all his effects and his literary remains to Dyson, who issued an edition of his poems in 1772. This included the revised version of the *Pleasures of Imagination,* on which the author was engaged at his death.

*See* Dyce's *Life of Akenside* prefixed to his edition of the *Poetical Works* (1835); also Johnson's *Lives of the Poets,* and C. Bucke, *Life, Writings and Genius of Akenside* (1832).

**AKERMAN, JOHN YONGE** (1806–1873), English antiquarian, distinguished chiefly in numismatics, was born in Wiltshire. He became early known in connection with his favourite study, having initiated the *Numismatic Journal* in 1836. In the following year he became secretary of the newly established Numismatic society. In 1848 he was elected secretary to the Society of Antiquaries, an office which he was compelled to resign in 1860 on account of failing health. Akerman published a considerable number of works on his special subject, the more important being a *Catalogue of Roman Coins* (1839); a *Numismatic Manual* (1840); *Roman Coins Relating to Britain* (1844); *Ancient Coins —Hispania, Gallia, Britannia* (1846); and *Numismatic Illustrations of the New Testament* (1846). He also wrote a *Glossary of Words Used in Wiltshire* (1842); *Wiltshire Tales, Illustrative of the Dialect* (1853); and *Remains of Pagan Saxondom* (1855).

**AKHALTSIKH** (Georgian *Akhaltsikhe*="New Castle"), a town in the Georgian S.S.R. It is situated in 41° 40′ N. and 42° 55′ E. at an altitude of 3,375 ft. on a tributary of the Kura river. The new town is on the right bank, the old on the left. Pop. about 15,000. Capital of the former province of Meschia or Samtskhe, it appears as a fief of the feudal house of Jaqeli *c.* 1203. By the 13th century, the Jaqelis acquired the whole principality of Meschia with the title of Atabegs (hence another name of the province: Saatabago). The separatist tendencies of Meschia first manifested in 1268 came to a break with the crown of Georgia under the Atabeg Quarquare II, who was referred to in the west as "duke of Akhaltsikhe" or "of Georgiana," in 1463. But in the 16th century the principality became tributary to the Ottoman empire. In 1625 the Atabeg Beka III turned Moslem and was created by the sultan pasha of Akhaltsikhe, which rank was borne by the rulers of Meschia until the Turkish suppression of this vassal principality in 1744. In 1828 Akhaltsikhe was taken by the Russians and the whole province incorporated in the Russian empire. There is trade in silk, honey and wax. Brown coal is found in the district. Its silver filigree work is famous. It is on the trade route to Turkey for caravans, but it has no railway communications. (*See* GEORGIA.)

**AKHENATON:** *see* IKHNATON.

**AK-HISSAR** or AKHISAR (anc. THYATEIRA, the "town of Thya"), a Turkish town situated in a fertile plain on the Gürdük Chai (Lycus), in the Manisa vilayet, 58 mi. N.E. of Smyrna. Pop. 22,739. Thyateira was an ancient town re-peopled with Macedonians by Seleucus about 290 B.C. It became an important station on the Roman road from Pergamum to Laodicea, and one of the "Seven Churches" of Asia (Rev. ii, 18), but was never a *metropolis* or honoured with a neocorate, though made the centre of a *conventus* by Caracalla. The modern town is connected with Smyrna by railway, and exports cotton, wool, opium, cocoons and cereals. Cotton of excellent quality is grown in the neighbourhood, and the place is celebrated for its scarlet dyes.

*See* W. M. Ramsay, *Letters to the Seven Churches* (1904); M. Clerc, *De rebus Thyatirenorum* (1893).

**AKHMIM,** a town of upper Egypt, on the right bank of the Nile, 67 mi. by river south of Asyut, and 4 mi. above Suhag, on the opposite side of the river. It has several mosques and two Coptic churches, maintains a weekly market, and manufactures cotton goods, notably the blue shirts and check shawls with silk fringes worn by the poorer classes of Egypt. Outside the walls are the scanty ruins of two ancient temples. In Abulfeda's days (13th century A.D.) a very imposing temple still stood here. Akhmim was the Egyptian Apu or Khen-min, in Coptic Shmin, known to the Greeks as Chemmis or Panopolis, capital of the 9th or Chemmite nome of upper Egypt. Herodotus mentions the temple dedicated to "Perseus" and asserts that Chemmis was remarkable for the celebration of games in honour of that hero, after the manner of the Greeks, at which prizes were given; but it is possible that he confused Coptos (*q.v.*) with Chemmis. Strabo mentions linen weaving as an ancient industry of Panopolis, and it is not altogether a coincidence that the cemetery of Akhmim is one of the chief sources of the beautiful textiles of Roman and Coptic age that are brought from Egypt. Monasteries abounded in this neighbourhood from a very early date. Nonnus, the Greek poet, was born at Panopolis.

**AKHTAL** (ahch-tahl′) (GHIYATH IBN HARITH) (*c.* 640–710), Arabian poet of the Omayyad period, belonged to the tribe of Taghlib in Mesopotamia, and was, like his fellow tribesmen, a Christian, enjoying the freedom of his religion, while not taking its duty very seriously. Akhtal, Jarir and Ferazdaq form a trio celebrated among the Arabs, but as to relative superiority there is dispute. Abu 'Ubaida placed him highest of the three on the ground that among his poems there were ten flawless *qasîdas* ("elegies"), and ten more which were nearly so, and that this could not be said of the other two poets.

BIBLIOGRAPHY.—P. A. Salhani, *Diwan de Aḫṭal Reproduction photolithographique du manuscrit de Bagdad, avec préface et variantes* (Beirut, 1905); Eugenio Griffini, *Le Dîwân d'al-Aḫṭal reproduit par la photolithographie s'après un manuscrit trouvé au Yemen, avec préface, glossaires . . .* (Beirut, 1907).

A full account of the poet and his times is given in H. Lammens' *Le chantre des Omiades* (Paris, 1895) (a reprint from the journal *Asiatique* for 1894).

**AKHTYRKA,** a town in the Ukrainian S.S.R. It is situated in 50° 20′ N. and 34° 52′ E. near the Vorskla river, on the railway from Kiev to Kharkov. Its beautiful cathedral, built in 1753, was designed by Rastrelli. It is a trade centre for fruit, sugar beet, corn, cattle and domestic woollen industries. It was founded by Poles in 1642. Population (1935) 27,302.

**AKKA** (TIKKI-TIKKI), a race of African pygmies first seen by the traveller G. A. Schweinfurth in 1870, in the Mangbettu country, northwest of Albert Nyanza. The home of the Akka is the dense forest zone of the Aruwimi district of the Congo state. They form a branch of the primitive pygmy Negroid race, and appear to be divided into groups, each with its own chief. The average height of the race would seem to be somewhat under four feet. They are of the colour of coffee slightly roasted, with hair almost the same colour, woolly and tufted; they have very projecting jaws, flat noses and protruding lips. An abdominal protuberance makes all Akka look like potbellied children, and the spine hollows into a curve like an **S.** These characteristics tend to disap-

pear. There is a tendency to steatopygia among the women. They are nomads, hunt game in the forests with poisoned arrows, with pitfalls and springs set everywhere, and with traps. They collect ivory and honey, manufacture poison, and exchange these for cereals, tobacco and iron weapons. In dress, weapons and utensils they are as the surrounding Negroes. They build round huts of branches and leaves in the forest clearings.

**AKKAD,** an ancient country (for the town sometimes called Akkad *see* under AGADE), northern Babylonia. The alluvial part of Mesopotamia was known in ancient times as Sumer and Akkad. Akkad was the narrow strip of land where the rivers approached one another most closely, and included the cities of Kish, Babylon, Sippar, Borsippa, Cutha (*qq.v.*) and Opis. For details *see* MESOPOTAMIA: *Ancient Geography.*

**AKKADIAN:** *see* ACCADIAN.

**AKKERMAN,** Rumania: *see* CETATEA ALBA.

**AKMOLINSK,** a town and province of the Kazakh Soviet S.R. The boundaries of the province are, north, northern Kazakstan; east, Pavlodar; south, Karaganda; west, Kustanaisk province. In the north the province is dotted with salt lakes, sloping south to a plateau (1,600 ft.), to the east of which is a spur formed by the dying out of the Tarbagatai range containing gold, copper and coal.

The Spasski copper mines are in the province and were restarted in 1925; near them are the Karagandinask coal beds, estimated at 6,000,000,000 tons; the two are connected by rail and are linked to the main railway.

The southeast is a wide, waterless desert the Bak-pak-dala or Hunger steppe. The climate is dry and continental, the rainfall (average 8–16 in.) is mostly in heavy thunderstorms, moistening the surface only. Dry, strong northeast winds, dusty in summer, prevail all the year, in winter as the Buran gale, sweeping the snow away and exposing the ground to five months of frost.

At Akmolinsk city (average temperature January 1.5° F., July 70° F.; yearly rainfall 9 in.), south of latitude 50°, the steppe is salty soil, with sparse wormwood, blue-gray grass, and plants with drought-resisting devices, hairs, pungent oils, thick leaves, etc., and animals such as suslik, hamster, jerboa and, rarely, saiga antelope. North of latitude 50° there is more moisture and better soil; in spring it is gay with tulips, irises, etc.; and in summer with white feather grass. The southern part of this area is inhabited by Kirghiz (in the Chu valley). The nomad Kara Kirghiz rear sheep, horses, camels, cattle and goats, following the pasture.

The city had a population in 1939 of 35,800.

Near the northern boundary of the province, wheat and barley are successfully grown, and the population consists mainly of Russian peasants. The town of Akmolinsk, on the Ishim river, is on the caravan routes from Tashkent and Bukhara to the north.

**AKOLA,** a town and district of India, in Berar, otherwise known as the Hyderabad Assigned Districts. The town is on the Murna tributary of the Purna river, Akola proper being on the west bank, and Tajnapeth, containing the government buildings and European residences, on the east bank. It had a pop. (1941) of 62,564. It is walled, and has a citadel built in the early years of the 19th century. Akola is one of the chief centres of the cotton trade in Berar, and has numerous ginning factories and cotton presses. Among the educational establishments are a government high school, and an industrial school supported by a Protestant mission.

The district of Akola as reconstituted in 1905 had an area of 4,093 sq.mi., the population of this area in 1941 was 907,742. The surface of the country is generally flat, the greater part being situated in the central valley of Berar. On the north it is bounded by the Melghat hills. By the addition of Basim and Mangrul *taluks* in 1905, the district includes the eastern part of the Ajanta hills, with peaks rising to 2,000 ft., and the tableland of Basim.

North of the Ajanta hills the country is drained eastward by the Purna affluent of the Tapti and its tributaries. The heat from April to mid-June is very great but even during the hot season the nights are cool. The annual rainfall averages 34 in. In the Purna valley the soil is everywhere a rich black loam particularly suitable to cotton, and nearly the whole of the land is cultivated. The history of Akola is not distinguished from that of the other portions of Berar.

**AKRON,** a city of Ohio, U.S., 35 mi. S.-by-E. of Cleveland, on the Little Cuyahoga river; the county seat of Summit county. It is about 1,200 ft. above sea level, on one of the highest spots in the state, whence its Greek name. The surrounding country is hilly and there are 20 lakes within 12 mi. of the city. On its northern boundary the Big Cuyahoga river flows through a gorge of great beauty, spanned by High Level bridge. A main approach from the north and east is by the North Hill viaduct, 135 ft. high and 2,810 ft. in length. Akron is served by the Baltimore and Ohio, the Erie, the Pennsylvania and the Akron, Canton and Youngstown railways. A belt line encircles the industrial section and the city is an important trucking centre. There are two municipal airports, one the site of Goodyear zeppelin dock, and the city is served by American, Capital, Eastern and United airlines. A naval air station is located in Akron. The Ohio canal, abandoned by commercial traffic, supplies water to some of the industries from lakes south of the city and serves as a pleasure route to the Portage lake state park near by. The city covers 55 sq.mi. Pop. (1950) 273,189; (1940) 244,791; (1930) 255,040.

The important period in Akron's history began about 1910. The town was settled about 1825 and incorporated as a village in 1836; became the county seat in 1842 and was chartered as a city in 1865. Through the 19th century it had a normal gradual development, at first because of its position on the Ohio canal, later because of the completion of the railway which is now the Erie and still later because of the manufacture of clay products and rolled oats. The pioneer rubber factory was established by B. F. Goodrich in 1870, and others came into existence with the extension of the uses of rubber for bicycle tires, heels and soles, beltings for machinery, elastic stockings, insulated wire and many other purposes. By 1900 the population had increased to 42,728, and in 1910 it was 69,067.

Then began a phenomenal growth. Between 1910 and 1920 the population of the city tripled. The aggregate value of its manufactured products rose from $73,158,000 in 1909 to $558,962,000 in 1919 ($575,000,000 in 1950); the average number of wage earners in the factories increased from 15,831 to 65,054 (85,000 in 1950). Postal receipts were quadrupled. All this was due chiefly to the demand for tires and other rubber products by the automobile industry. Akron's rubber factories at mid-20th century were producing more than 50,000 articles, ranging from rubber bands to balloons and dirigibles, and including 65% of the total U.S. output of tires. Normally Akron rubber factories account for approximately 40% of the annual U.S. consumption of crude rubber.

The older industries (oatmeal, matches and sewer pipes, machine tools, etc.) are still important. The town produces also puffed grains for breakfast foods, chemical stoneware, porcelain insulators, fishing tackle, rubber factory equipment, steel automobile rims, automobile batteries, wood products, plasters and chemicals. Salt and sulphur are refined, and zinc oxide is produced.

The production of synthetic rubbers became a major industry during World War II. Parts for aeroplanes also are fabricated there.

The rapid industrial development stimulated progress in other directions. Expenditures by the city for health and sanitation increased from $53,231 in 1910 to $795,100 in 1950; sanitation and health from $277,454 to $9,970,498. A municipal water system and a sewage-treatment plant were provided a cost of $125,000,000 and an imposing municipal building was erected. Experts surveyed the public-school system (1917) and prepared a city plan (1919). A city planning commission created in 1920 secured the adoption of a zoning ordinance in 1922. More than 4,300 ac. of park area are in or near the city, including a fine municipal golf

course. The Portage lakes also provide excellent recreation sites. From 1920 the charitable agencies were jointly financed by a "community chest" operated by the Better Akron federation.

The University of Akron, which is a part of the free public-school system of the city, was created in 1913, when the city council accepted as a nucleus the plant and endowment of Buchtel college, which had been founded in 1870 and named after its chief benefactor, John R. Buchtel (1822–92), a businessman of Akron. Fellowships for research in the chemistry of India rubber were established by the Goodyear and the Firestone Tire and Rubber companies. At mid-20th century the annual enrolment in the university was about 4,500.

Because of the dominating industries Akron's population has tended to have a preponderance of men, a high proportion of skilled and semiskilled labour; relatively high wages; and a high proportion of men engaged in gainful occupations. The population was not congested, even after the period of rapid growth. Small detached or semidetached dwellings are the rule. At mid-20th century, approximately 70% of the homes were owned by their occupants.

A "home rule" charter went into effect Jan. 1, 1920. Under it Akron adopted the city-manager form of government, but after four years this was discarded and the executive duties were transferred to a mayor elected at large. The old Portage trail, used by the Indians in carrying their canoes from the Cuyahoga river to the Tuscarawas river in the journey from Lake Erie to the Ohio, runs through the city. It is marked at each end by commemorative tablets and bronze figures of Indians. A house once occupied by John Brown, the abolitionist, is in the western part of the city.

**AKSAKOV, SERGEI TIMOFEYEVICH** (1791–1859), Russian writer, grandson of Sergei Aksakov, a country squire who founded a colony in the Bashkir steppe, was born at Ufa, Orenburg, on Sept. 20, 1791, and died in Moscow on April 30, 1859. He studied at the University of Kazan, and in 1808 entered the civil service in St. Petersburg (Leningrad). In 1815 he married and returned to the Urals to cultivate his estate. He dissipated his fortune after ten years of estate management, and found, through the influence of Shishkov, a place in the censorship at Moscow. There his house became a centre of Slavophilism. In 1832 he met Gogol, in whom he recognized a genius unspoiled, as he thought, by foreign influence. His friendship with Gogol led him to write himself, and, though that friendship was clouded in later years, it is to Gogol that Aksakov owed his inspiration. Aksakov draws on the history of his pioneer grandfather, a great figure of the family autocrat in a primitive community, wonderfully depicted, with the marriage of his own father and mother, and with his own schooldays. All these books are Russian classics. They give a picture of Russian rural life before the liberation of the Serfs remarkable in itself, and beautiful because of the author's keen, sensuous appreciation of nature, but interesting from the purely literary point of view in the development of the novel. Aksakov, to quote Prince Mirsky, "came nearer than any other Russian writer, even than Tolstoy in *War and Peace*, to a modern, evolutionary, continuous presentation of human life, as distinct from the dramatic and incidental presentation customary to the older novelists."

His best known works are: *Chronicles of a Russian Family* (1856, tran. by M. C. Beverley, 1924); *Recollections* (1856), tran. by J. D. Duff under the title: *Autobiography of a Russian Schoolboy* (1917, repr. 1924); *Years of Childhood* (1858: tran. by J. D. Duff, 1916, repr. 1923). Aksakov's other important work is his *Recollections of Gogol*, which is the most important contemporary record of that great writer.

His elder son, KONSTANTIN SERGEYEVICH AKSAKOV (1817–1860), Slavophil author, was born at Moscow on April 10, 1817, and died in the Island of Zante in Greece on Dec. 19, 1860.

His younger son, IVAN SERGEYEVICH AKSAKOV (1823–1886), Russian Slavophil writer, was born at Nadezhdin in Ufa, on Sept. 26, 1823, and died at Moscow on Jan. 27, 1886. He studied law at St. Petersburg, and later entered the Moscow division of the senate. At various periods he edited or established weekly and daily papers, the Moscow *Sbornik*, the *Den* (1861–65), the *Moskva* (1867), which was three times suppressed by the government, and later, in 1880, the *Rus*, an organ of the Slavophil party. Between 1840 and 1860 Aksakov wrote numerous radical and political poems. His realistic poem *The Tramp* (1852), depicted the life of the Russian peasant. The height of Aksakov's activity as leader of the Panslavist movement was reached in 1876–78, when he warmly supported the cause of the liberation of the Balkan Slavs. In 1878 he was exiled from Moscow for a violent attack on the treaty of Berlin in a speech delivered at the Slavic committee; but he was soon allowed to return, and continued to publish the *Rus* until his death.

**AKSHAK,** a city in northern Sumer (now Iraq), 34° N., 44° E. There was a prehistoric Sumerian city on this site which lay on the Tigris at the mouth of the river Adhem (Physcus). It was the most northerly of the Sumerian cities and appears in the dynasty lists between Maer and the 4th dynasty of Kish. The site is usually identified with the Opis of Xenophon, who states that it was a large and populous city and that the Physcus was here spanned by a bridge, but Rawlinson identified Opis with another ancient site south of the Diyala, near Baghdad.

**AK-SHEHR** or AKSEHIR (anc. PHILOMELION), town, Konia vilayet, Turkey, at the edge of a fertile plain, on the north side of the Sultan Dagh. Philomelion was probably a Pergamenian foundation on the Graeco-Roman highway from Ephesus to the east, and to its townsmen the Smyrniotes wrote the letter that describes the martyrdom of Polycarp. Cicero, on his way to Cilicia, dated some of his extant correspondence there; and the place was important in frontier wars between Byzantine emperors and the sultanate of Rum. It became an important Seljuk town, and late in the 14th century passed into Ottoman hands. There Bayezid Yilderim is said by Ali of Yezd to have died after his defeat at Angora. The place still enjoys much repute among Turks as the burial place of Nasr-ed-din Hodja. The town has a station on the Anatolian railway, about 60 mi. from Afiun Qarahisar and 100 mi. from Konia. Pop. (1940) 12,502.

**AKSU:** *see* TURKISTAN.

**AKSUM** (previously AXUM), an ancient city in Tigré, Abyssinia, 14° 8′ N., 38° 31′ E., altitude 7,226 ft., 12 mi. W. by S. of Aduwa. The old Abyssinian Book of Aksum contains the native legend of its foundation many thousands of years ago; the first authoritative mention of it, however, is in the *Periplus Maris Erythraei* (*c.* A.D. 67) where it is referred to as the seat of the Axumite kingdom, the successor of the more ancient Punt and the forerunner of the modern Abyssinia. (*See* ETHIOPIA.)

It contains the ancient church where, according to tradition, the *Tobot* or Ark of the Covenant, brought from Jerusalem by the son of Solomon and the Queen of Sheba, was deposited and is still supposed to rest. The church was burned when Axum was sacked by Mohammed Gran the Moslem invader of Abyssinia in about 1535 and a new one was erected by the Portuguese shortly afterward. It is famous for the ancient inscriptions in Minaco Sabaean, a Gîz script of the 4th and 5th centuries and for its stone obelisks, many of which are still standing. They form a consecutive series from rude unhewn stones to highly finished obelisks, of which the tallest still erect is 60 ft. in height, with 8 ft. 7 in. extreme front width; others that are fallen may have been taller. The highly finished monoliths are all representations of a many-storied castle, with an altar at the base of each. They appear to be connected with Semitic sun-worship and are assigned by J. T. Bent to the same period as the temple at Baalbek.

BIBLIOGRAPHY.—Classical references, Pietschmann in Pauly's *Realencyklopädie* (2nd ed.); History from inscriptions, *see* D. H. Müller, Appendix to J. T. Bent's *Sacred City of the Ethiopians* (1893), and E. Glaser, *Die Abessinier in Arabien* (Munich, 1895); Antiquities, Bruce's *Travels* (1790); Salt, in the *Travels of Viscount Valentia*, iii, 87–97 and 178–200 (1809); J. T. Bent *op. cit.* and A. B. Wylde, *Modern Abyssinia* (1901).

**AKTUBINSK,** formerly part of the Turgai region, now a region in the Kazakh Soviet Socialist Republic. Area 176,632.6 sq.mi. The boundaries are, on the north, Chkalov and Kustanaisk; west, Adaev and Uralsk; south, Adaev, the Aral sea and Syr-Darya; east, Akmolinsk. It is divided for administrative purposes into Aktubinsk, pop. 238,059 (urban 20,504); Temirsk, pop. 77,-

799, (urban 4,000); Turgai, pop. 94,304, (urban 1,836); Chelkarsk, pop. 90,376 (urban 6,716). South of the east to west stretch of the Ural river, the Ural mountains continue as a plateau, the southward termination of which (the Mugojar hills) is deeply dissected by the streams of the craggy southeastern slopes, a former shore line of the Aral sea. Beneath these slopes the streams lose themselves in the saline steppes that fringe the Aral sea and extend far northeast as part of the Turgai steppe. The climatic conditions are increasingly dry (av. rainfall four to eight inches), and the prevailing northeast winds bring sandstorms in summer and dry snow in winter, a season otherwise of cloudless skies and bitter cold, while the summer temperature averages 85° F. The numerous lakes are surrounded by reeds, the haunt of the wild boar, with grass patches in places; the stream shores are also grassy, especially in spring, and attract geese and cranes. The steppe includes black-earth areas carrying feather grass, clays bearing wormwood, salt clays with salsolaceae vegetation and bare shifting sand hills. Wild cherry and almond grow on the hillsides. The steppe fauna includes jerboa, marmot, steppe fox and saiga antelope. Famines are frequent for lack of irrigation and scientific crop rotation, though rye, wheat, oats, barley and potatoes are grown. Nomadic herding of sheep, horses, camels and cattle is the chief occupation, and there is change of ground between the spring-and-summer grazing area of the Turgai steppe and the winter shelters in the Syr-Darya area. Cattle and hides are exported to Orenburg and camels are bred for the caravan transport between Bukhara, Khiva and Russian Turkistan. Sunflower-seed oil, flour and leather are produced for local use and salt is obtained from the lakes, while *koustar* (home) industries in felt products and carpets are widespread. The Emba river naphtha area extends into the southwest of the region and has its centre at Emba. In the northwest, near the Ulek river, coal is mined. Aktubinsk, the chief town, is on the Chkalov-Tashkent railway.

**AKYAB,** a municipality and district in the Arakan province of Burma at the confluence of the large rivers Mayu, Kaladan and Lemro. After the cession of Arakan to the British by the treaty of Yandaboo in 1826 the old capital of Myohaung was abandoned as the seat of government, and Akyab on the sea coast selected instead. Trade restrictions were removed and Akyab rapidly grew from a small fishing village into a leading port of Burma, with a population in 1931 of 38,094 (28,724 males and 9,370 females). The population has varied but slightly after the census of 1881. Out of the total population 4,049 (3,877 males and 172 females) are "adventitious" Mohammedan and Hindu labourers. The settled civil population comprises 15,802 Buddhists (Arakanese and Burmese, 8,111 males and 7,691 females), 10,988 Hindus (10,259 males and 729 females) and 10,032 Mohammedans (9,456 males and 576 females).

It contains the usual public buildings and several large rice mills. The chief export is rice. The district lies along the northeastern shores of the Bay of Bengal, with an area of 5,176 sq.mi. and a population in 1941 of 760,705. (*See* BURMA.)

**ALA,** one of the side recesses which usually opened off the atrium (*q.v.*) of a Roman house. One was placed on each side in the corners off the back of and entirely open to the atrium. The term applies also to the wings, open their entire width in front, at each side of the cella in one of the Tuscan temple plans (Vitruvius iv, 7). In physiology, any winglike process such as one of the lateral cartilages of the nose (Lat. *ala,* a wing). In botany, one of the side petals of a papilionaceous corolla, etc.

**ALABAMA,** called the "Cotton state" because of its chief agricultural product, a southern state of the U.S.A., is situated between approximately 84° 51′ and 88° 28′ W. and 30° 13′ and 35° N., and is bounded N. by Tennessee, E. by Georgia, S. by Florida and the Gulf of Mexico, and W. by Mississippi. Its total area is 51,609 sq.mi., of which 531 are water surface.

**Physical Features.**—Northern Alabama is a diversified region, invaded by the Appalachian highlands. In the northeast Lookout, Raccoon and Sand mountains are important physical features. The rugged Cumberland plateau, extending deeply into the state from Tennessee, is crossed from east to west by the fertile Tennessee valley. The great Appalachian valley and the Piedmont plateau invade the state for a considerable distance from the Georgia line.

THE GREAT SEAL OF THE STATE OF ALABAMA, ADOPTED BY ACT OF THE LEGISLATURE AND APPROVED ON APRIL 5, 1939

The Tennessee and Coosa rivers, draining the highlands, provide an important power resource. A belt of prairie country crosses the central portion of the state from east to west, while further south lies the Gulf coastal plain, which slopes gradually down to sea level in the south, where it touches the Gulf of Mexico. The rivers of the coastal plain are the Tombigbee and Black Warrior in the west, the Alabama in the central west, and the Chattahoochee, which forms almost half of the Georgia boundary, in the east. The Tombigbee and the Alabama unite in the southwest; their waters then part to flow into Mobile bay as the Mobile and Tensas rivers. The valleys of the coastal plain are broad and in most cases rise in three successive terraces above the streams. The bay of Mobile averages about 12 ft. in depth, though there is a deep anchorage near the entrance, some 30 mi. below the city of Mobile. In 1951 a dredged channel 33 ft. deep reached from the bay entrance to the extensive port facilities of Mobile.

**Climate and Soil.**—Alabama has a temperate climate. The average mean temperature for the state in winter is 46° F. and in summer 79° F. In the winter, on the average, 35 days have temperatures below the freezing point; snow falls only once or twice a year in the northern part. The prevailing winds are from the south. Rainfall is fairly evenly distributed throughout the state, the annual average being about 52 in.; thunderstorms are numerous in summer. The rainy season is in the winter, however, and the dry season in late summer and fall.

There are four different belts of soil. In the timber belt along the coast the soil is sandy and generally poor but responds to fertilization. North of this lies the black belt ("black prairie" "cotton belt"), 13,000 sq.mi. in extent which has black soil that is rich in limestone and marl formations, without sand or loam and is especially adapted to the production of cotton and grasses. Between the cotton belt and the Tennessee valley lies the mineral belt, the soils of which are of varied fertility. North of the mineral belt is the cereal belt in the Tennessee valley, containing red clays and dark loams.

**History.**—The first Europeans to enter the limits of the present state of Alabama were Spaniards, who claimed the region as a part of Florida. The first fully authenticated visit was that of Hernando de Soto, who journeyed along the Coosa, Alabama, and Tombigbee rivers in 1539–40. The English, too, claimed the region north of the Gulf of Mexico, and the territory of modern Alabama was included in the province of Carolina by the charters of 1663 and 1665. English traders from Carolina were frequenting the valley of the Alabama river as early as 1687. Mobile, the first permanent white settlement in Alabama, was founded by the French in 1702. Later, on account of intrigues between English traders and the Indians, the French established two military posts.

The treaty of Paris, in 1763, terminated the French occupation and England came into undisputed possession of the region between the Chattahoochee and the Mississippi. The portion of Alabama below line 32° 28′ N. became a part of west Florida and the portion north of this line a part of the "Illinois country," set apart by royal proclamation for the use of the Indians. By the treaty of Versailles, on Sept. 3, 1783, England ceded West Florida to Spain; but by the treaty of Paris, signed the same day, it ceded to the United States all of this province north of 31°, and thus laid the foundation for a long controversy. By the treaty of Madrid, in 1795, Spain ceded to the United States claims to the lands east of the Mississippi between 31° and 32° 28′; and three years later (1798) this district was organized by congress as the Mississippi territory. A strip of land 12 or 14 mi. wide near the present northern boundary of Alabama and Mississippi was claimed

by South Carolina which, however, ceded this claim to the federal government in 1787.

Georgia, on the basis of its charter, claimed all the lands between the 31st and 35th parallels from its present western boundary to the Mississippi river, a claim not surrendered until 1802; two years later the boundaries of the Mississippi territory were extended to include all of the Georgia cession.

In 1813 congress annexed to the Mississippi territory the Mobile district of West Florida, claiming that it was included in the Louisiana purchase. The whole area of the present state of Alabama then for the first time became subject to the jurisdiction of the United States. In 1817 the Mississippi territory was divided; the western portion became the state of Mississippi, and the eastern the territory of Alabama, with St. Stephens, on the Tombigbee river, as the temporary seat of government. In 1819 Alabama was admitted to the union.

One of the first problems of the new commonwealth was that of finance. Since the amount of money in circulation was insufficient to meet the demands of the increasing population, a system of state banks was instituted. State bonds were issued and school land sold to secure capital. The notes of the banks, loaned on security, became a medium of exchange. Prospects of an income from the banks led the legislature of 1836 to abolish all taxation for state purposes. This was hardly done, however, before the panic of 1837 wiped out a large portion of the banks' assets; next came revelations of careless and corrupt management, and in 1843 the banks were placed in liquidation. After disposing of all their available assets, the state assumed the remaining liabilities, for which it had pledged itself.

The Indian problem was important at this time. With the encroachment of the white settlers upon their hunting grounds the Creek Indians grew restless, and the great Shawnee chief Tecumseh, who visited them in 1812, fomented their discontent. When outbreak of the War of 1812 with Britain gave the Creeks assurance of British aid, many of them rose in arms, massacred several hundred settlers who had taken refuge in Fort Mims, below the junction of the Alabama and Tombigbee rivers, and soon no white family in the Creek country was safe outside a palisade. The Chickasaw and Choctaw Indians, however, remained the faithful allies of the whites and volunteers from Georgia, South Carolina and Tennessee helped to put down the Creeks.

Gen. Andrew Jackson broke forever the power of the Creek confederacy in the battle of Horseshoe Bend. By the treaty of Fort Jackson (Aug. 9, 1814) the Creeks ceded their claims to about one-half of the present state; and further cessions by the Cherokees, Chickasaws and Choctaws left the Indians only about one-fourth of Alabama. By a series of treaties with the Indians, between 1830 and 1835, the U.S. government arranged for their removal to the west. Before the contract for the removal of the Creeks was effected, the state legislature formed their lands into counties and settlers flocked in. A disagreement ensued between Alabama and the United States authorities; although it was amicably settled, it engendered a feeling that the policy of the national government might not be in harmony with the interests of the state —a feeling which, intensified by the slavery agitation, did much to cause secession in 1861.

*Political History.*—The political history of Alabama may be divided into three periods—that prior to 1860, from 1860 to 1874, and from 1874 onward.

The first period was one of a healthy and virile political life. Until 1832 the Democratic party was the only party in the state, but about the same time the Whig party was formed chiefly in counties where slaves were most numerous and the freemen most aristocratic. For some time the Whigs were nearly as numerous as the Democrats, but they never controlled the state government. The states' rights men were in a minority; nevertheless, under their active and persistent leader, W. L. Yancey (1814–1863), they prevailed upon the Democrats in 1848 to adopt their most radical views.

During the agitation over the introduction of slavery into the territory acquired from Mexico, Yancey induced the Democratic state convention of 1848 to adopt the "Alabama platform," which declared that neither congress nor the government of a territory had the right to interfere with slavery in a territory, that those who held opposite views were not Democrats and that the Democrats of Alabama would not support a candidate for the presidency if he did not agree with them on these questions. This platform was endorsed by conventions in Florida and Virginia and by the legislatures of Georgia and Alabama. Old party lines were broken by the compromise of 1850. The states' rights men founded the Southern Rights party, which demanded the repeal of the compromise, advocated resistance to future encroachments and prepared for secession, while the Whigs, joined by the remaining Democrats, formed the party known as the "Unionists," which unwillingly accepted the compromise and denied the constitutional right of secession. The Unionists were successful in the elections of 1851 and 1852, but the feeling of uncertainty engendered in the south by the passage of the Kansas-Nebraska bill and the course of the slavery agitation after 1852 led the State Democratic convention of 1856 to revive the Alabama platform; and when the Alabama platform failed to secure the formal approval of the Democratic national convention at Charleston, South Carolina, in 1860, the Alabama delegates, followed by those of the other cotton states, withdrew. Upon the election of Abraham Lincoln, Gov. Andrew B. Moore, in obedience to previous instructions of the legislature, called a state convention on Jan. 7, 1861. After long debate it adopted on Jan. 11 an ordinance of secession, and Alabama became one of the Confederate states of America, whose government was organized at Montgomery Feb. 4, 1861. Yet many prominent men opposed secession, and in northern Alabama, where there were relatively few slaves, an attempt was made to organize a neutral state, Nickajack; but with President Lincoln's call to arms opposition to secession ended.

In the early part of the Civil War, Alabama was not the scene of military operations, yet the state contributed about 120,000 men to the Confederate service, almost all its male white population capable of bearing arms; 39 of these men attained the rank of general. In 1862 the Federal forces secured a foothold in northern Alabama. The interior of the state was subjected to several raids after 1862, and in 1865 Mobile was taken by a Federal fleet and army. Several days before the fall of Mobile, Selma was sacked by the Wilson raiders.

According to the presidential plan of reconstruction, a provisional governor for Alabama was appointed in June, 1865; a state convention met in September and declared the ordinance of secession null and void and slavery abolished; a legislature and a governor were elected in November; the legislature was at once recognized by the national government, and the inauguration of the governor-elect was permitted after the legislature had, in December, ratified the 13th amendment. But the passage by the legislature of vagrancy and apprenticeship laws designed to control the Negroes flocking from the plantations to the cities intensified the congressional hostility to the presidential plan and the Alabama senators and representatives were denied their seats in congress. In 1867 the congressional plan of reconstruction was completed and Alabama was placed under military government. Negroes were now enrolled as voters and large numbers of white citizens disfranchised. "Carpet-baggers" from the north organized the Republican party on the basis of Negro votes and the support of native whites called "scalawags." A constitutional convention controlled by the carpet-baggers met in Nov., 1867, and framed a constitution which conferred suffrage rights on Negroes and disfranchised a large class of whites. The constitution was defeated by the whites, who stayed away from the polls, thus preventing the required majority of registered voters from voting. Congress, however, provided subsequently that a majority of the votes cast should be sufficient, and thus the constitution went into effect. The state was admitted to the union in June, 1868, and a new governor and legislature were elected.

The next two years are notable for legislative extravagance and corruption. The state endorsed railway bonds at the rate of $16,000 a mile until the state debt had been increased by $17,000,000, and similar extravagance characterized local government. The native white people united, formed a conservative

party, and elected a governor and a majority of the lower house of the legislature in 1870; but, as the new administration was largely a failure, there was in 1872 a reaction in favour of the "radicals," as the Republicans were locally known. Affairs went from bad to worse. In 1874, however, the power of the radicals was finally broken and the conservative Democrats elected all state officials. A commission appointed to examine the state debt found it to be $32,000,000; by compromise it was reduced to $12,413,514. A new constitution was adopted in 1875, which gave equal civil and political rights to all citizens and forbade the state, counties and towns to engage in internal improvements or to give their credit to private enterprise.

After 1874 the Democratic party controlled the state administration. The Republicans usually did not make nominations for state office. They endorsed the tickets of the Greenback party in 1880 and 1882 and of the Populists in the 1890s. Economic distress among the farming classes found expression in the Jeffersonian Democratic party, organized in 1892. After the regular Democratic ticket was elected in that year, however, the Jeffersonians and Populists joined forces in the election of 1894. When, at the same time, the Republicans united with the Populists and Jeffersonians, the combination elected three congressional representatives and secured control of many of the counties but failed to carry the state. It was less successful in the next few campaigns. Partisanship became intense and charges of corruption of the Negro electorate were made. Consequently, after division on the subject among the Democrats themselves, as well as opposition from Republicans and Populists, a new constitution with restrictions on suffrage was adopted in 1901. The new restrictions resulted in the virtual elimination of the Negro vote and, therefore, in a reduction of the Republican vote. The Republican party, which had polled 54,737 votes in the presidential election of 1896 and 55,634 votes in the election of 1900, polled only 22,472 votes in the election of 1904. Its vote remained at about that level until 1920, when the effects of economic changes began to appear in elections. In the presidential election of that year the Republican vote was 74,690, or 31.9% of the vote cast—more than enough to secure the privilege of a primary for the nomination of candidates in the next election at the expense of the state government. The gains of the Republican party were registered chiefly in the growing industrial districts and in the counties round about, such as Chilton, De Kalb, St. Clair and Winston, in which the party polled majorities, and in Blount, Clay, Cullman, Marshall and Shelby, in which it polled strong minorities. Although its vote fell off to 45,005 in 1924, the striking increase in the Republican vote in the preceding 20 years and the appearance of a Socialist vote were considered by many the normal result of industrial development and by some as a sign of a future breakup of the "solid South."

The strength of the Republican party remained in the hill counties of the state. The threatening poll of 120,724 for Hoover in 1928 was largely the result of sectarian hostility to Smith and to his opposition to prohibition. Yet he carried the state by about 7,000 votes.

Franklin D. Roosevelt won easily in 1932 by 207,910 to 34,674; in 1936 by 238,195 to 35,358; in 1940 by 250,723 to 43,493; and in 1944 by a wide margin. In 1948 the Democratic electors, having pledged themselves not to vote for the election of Harry S. Truman, cast their votes for Gov. J. Strom Thurmond of South Carolina, running on the States' Rights Democrat ticket; Thurmond received 171,443 popular votes and Thomas E. Dewey, Republican, 40,930.

Three important amendments, pertaining to education and highways, were added to the constitution of 1901: one provided for local option by counties and school districts as to increased taxation for public schools; each of the other two (one in 1922 and the other in 1927) authorized the issue of state bonds to the amount of $35,000,000 for the construction of a complete system of highways, thus securing for the state the national appropriations in aid of that policy. The problems of the depression in the early 1930s compelled several emergency measures and permanent reforms. A special convention voted for repeal of the federal prohibition amendment; a special legislature proposed an amendment to the constitution to validate about $17,000,000 in outstanding state warrants largely held by teachers and another to provide a state income tax; both of these measures were ratified by popular vote.

The legislature of 1939 proposed amendments for the improvement of the system of pardons and paroles and for biennial sessions of the legislature, which were ratified. This same legislature enacted a state civil service law, and passed acts for the reorganization of the state government for the purpose of eliminating duplication of work and providing better administration.

**Government.**—The constitution of the state was drafted in 1819 and revised in 1865, 1868, 1875 and 1901. The revision of 1901 lengthened the term of executive and legislative officials from two to four years, made that of the judiciary six years, provided for quadrennial sessions of the legislature (changed to biennial sessions by an amendment of 1939), and introduced the office of lieutenant governor. The passage of local or special bills by the legislature was generally prohibited. A provision, intended to prevent lobbying, prohibited anyone except legislators and representatives of the press from being admitted to the floor of the house except by unanimous vote. No executive official might serve two consecutive terms (sheriffs were included in this provision until exempted by an amendment of 1939), and the governor could not be elected or appointed to the U.S. senate or to any state office during his term as governor or within one year thereafter. Sheriffs whose prisoners suffered mob violence might be impeached.

The constitution of 1901 eliminated most of the Negroes from politics by a suffrage clause which went into effect in 1903, restricting the right to vote to those who could read and write any article of the constitution of the United States and who had been regularly engaged in some lawful employment, business or occupation, trade or calling for the greater part of the 12 months preceding the time they offered to register, or who had paid taxes on property assessed at $300. But by what was called the "grandfather clause" those who had served in the army or navy of the United States or of the Confederate states in time of war, their lawful descendants in every degree, and persons of good character who understood "the duties and obligations of citizenship under a republican form of government" were relieved from the operation of this law, provided they registered prior to Dec. 20, 1902. The constitution of 1901 (like that of 1875) and special statutes enacted thereunder required separate schools for white and Negro children. A "Jim Crow" law had been enacted in 1891.

Under the constitution of 1901 no person under 45 might vote who had not by Feb. 1 preceding an election paid all poll taxes due from him to the state (constitutional amendments of 1923, 1924 and 1944 exempted veterans of World Wars I and II). The penalty for buying, selling, or offering to buy or sell a vote was disfranchisement; in 1891 the Australian ballot system was adopted.

The constitution of 1901 exempted a homestead of 80 ac. of farmland or of a house and lot not exceeding $2,000 in value from liability for any debt contracted since July 30, 1868, except for a mortgage on it to which the wife consented; personal property to the value of $1,000 was also exempted. All amendments to the constitution had to be approved by a three-fifths vote of each house of the legislature and then ratified by the people.

Under the civil code of 1897 the earnings of a wife were made her separate property, and it was provided that "no woman, nor any boy under the age of 12 years, shall be employed to work or labor in any mine in this state." By acts of 1915 and 1919 restrictions were placed upon the employment of children under 14. An amendment of 1947 provided that no child under 16 might be employed in any gainful occupation except agriculture and domestic service; no child under 16 might be employed during school hours, and no child under 16 might be employed on or near dangerous machinery or more than 40 hours per week, except in agriculture.

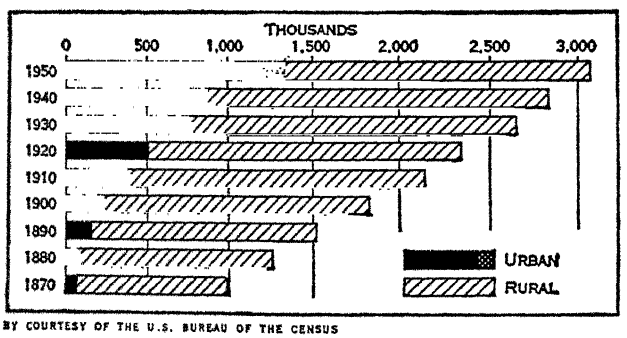
Any person or firm violating these provisions was subject to

fines, and the child welfare department with a local board of child welfare in each county was available to see to the enforcement of the law.

**Population.**—The population of Alabama in 1820 was 127,901; in 1860 it was 964,201; in 1900, 1,828,697; in 1940, 2,832,961; and in 1950, 3,061,743. This last figure represents an increase of 8.1% over the population in 1940. The population per square mile in 1950 was 59.9, as compared with 55.5 in 1940, and with 50.6 for the U.S. in 1950.

Of the 1950 population, 1,228,209, or 40.1%, lived in incorporated places of 2,500 or more, as compared with 30.2% in 1940, when these places constituted the urban area. The entire urban population, under a new definition set up for 1950, which included also the thickly settled suburban area, or "urban fringe," adjacent to Birmingham, Mobile and Montgomery, and nine unincorporated places of 2,500 or more outside this fringe, amounted to 1,340,937, or 43.8% of the state total.

TABLE I.—*Population of Alabama and Its Principal Cities, 1930-50*



| Area | Population | | | Per cent of increase | |
|---|---|---|---|---|---|
| | 1950 | 1940 | 1930 | 1940–50 | 1930–40 |
| The state | 3,061,743 | 2,832,961 | 2,646,248 | 8.1 | 7.1 |
| Urban | 1,340,937* | 855,941 | 744,273 | 56.7 | 15.0 |
| Rural | 1,720,806* | 1,977,020 | 1,901,975 | −13.0 | 3.9 |
| Per cent urban | 43.8 | 30.2 | 28.1 | — | — |
| Principal cities | | | | | |
| Birmingham | 326,037 | 267,583 | 259,678 | 21.8 | 3.0 |
| Mobile | 129,009 | 78,720 | 68,202 | 63.9 | 15.4 |
| Montgomery | 106,525 | 78,084 | 66,079 | 36.4 | 18.2 |
| Gadsden | 55,725 | 36,975 | 24,042 | 50.7 | 53.8 |
| Tuscaloosa | 46,396 | 27,493 | 20,659 | 68.8 | 33.1 |
| Anniston | 31,066 | 25,523 | 22,345 | 21.7 | 14.2 |
| Bessemer | 28,445 | 22,826 | 20,721 | 24.6 | 10.2 |

*Final figures based on new definition. *See* comment in text.

The number of households in 1950 was 786,467, as compared with 673,815 in 1940. The average population per household had declined from 4.2 in 1940 to 3.9 in 1950.

The population of the state was distributed by colour and nativity in 1950 as follows: 67.5% native white; 0.5% foreign-born white; and 32.0% nonwhite, practically all Negro. There were 98.6 males per 100 females in the native white population, and 91.7 in the Negro population; 6.5% of the population was 65 years old or over; and 51.2% of the population 14 years old and over was in the labour force.

Of the total number of employed males, 29.4% was engaged in agriculture, 24.2% in manufacturing and 18.5% in transportation and trade.

URBAN AND RURAL POPULATION OF ALABAMA: 1870 TO 1950
The crosshatched part of the 1950 bar represents the population of the additional areas counted as urban under the new 1950 definition

**Finance and Taxation.**—Formerly a large part of the state's revenue came from a general property tax, but as a result of a gradual change this source provided only 4.1% of the state government's revenue in 1949. Other principal sources in 1949 were the sales tax (18.8%), gasoline tax (17.0%), income tax (8.2%), tobacco tax (4.1%), motor vehicle licence tax (3.4%), profits from state liquor stores (6.9%) and federal grants for roads, health, schools, conservation, welfare, etc. (20.6%), the total receipts being $174,391,524.64.

TABLE II.—*State Expenditures, 1949*

| | Disbursement | Per cent of total |
|---|---|---|
| General government | $6,103,026.68 | 3.5 |
| Protection to person and property | 6,123,605.19 | 3.5 |
| Highways | 25,965,298.24 | 14.9 |
| Development and conservation of natural resources | 3,737,978.83 | 2.2 |
| Health and sanitation | 4,202,918.74 | 2.4 |
| Hospitals and institutions for the handicapped | 4,219,444.22 | 2.4 |
| Public welfare | 25,830,676.76 | 14.8 |
| Correction | 4,459,381.29 | 2.6 |
| Education | 63,853,743.13 | 36.6 |
| Libraries | 92,956.02 | 0.05 |
| Recreation | 71,400.06 | 0.04 |
| Liquor stores | 2,138,930.71 | 1.2 |
| Debt service | 3,733,086 25 | 2.1 |
| Payments to counties | 19,251,147.87 | 11.1 |
| Payments to cities | 4,520,310.89 | 2.6 |
| Total | $174,303,904.88 | 100.0 |

Figures given do not cover city and county receipts and disbursements except as indicated.

The framers of the constitution of 1901, thinking to avoid a repetition of the reckless borrowing of the reconstruction period, prohibited an increase of the state's debt for any other purpose than the suppression of rebellion or resistance to invasion, but amendments later provided for the floating of special loans for certain internal improvements.

**Education.**—Public education, authorized for Mobile alone in 1826 and inaugurated there in 1852, was extended to the whole state in 1854. Previously there had been a township system, which received support from special taxes fixed by each township and from the sale of public lands given to the state by the federal government.

BY COURTESY OF THE U.S. BUREAU OF RECLAMATION

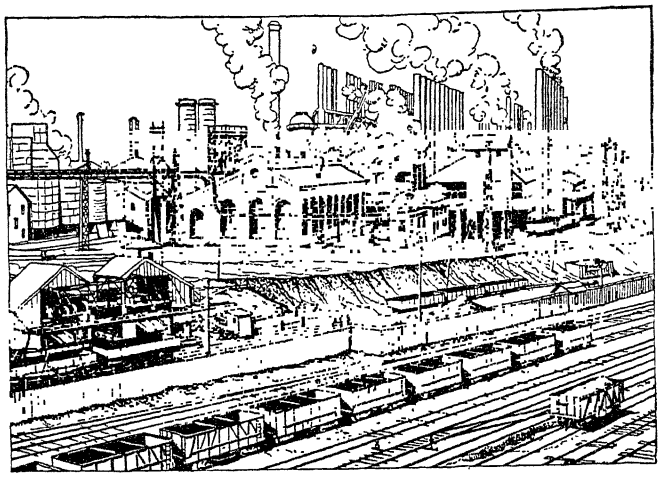
HOME OF A NEGRO FARM TENANT

The constitution of 1875 made the support of the schools dependent upon the land grant of 1819, the poll tax and state appropriations; it established separate schools for Negroes and whites. The constitution of 1901 made obligatory a state tax of from 30 to 65 cents on each $100 worth of property to be expended on education. The legislature of 1907 voted an increase of $300,000 for the common school fund, granted state aid for rural school buildings and established a system of county high schools. A constitutional amendment in 1915 allowed the counties to levy a special school tax. In 1948–49 the state board of education disbursed $56,917,948 for elementary and secondary education and the state teachers' colleges.

Illiteracy decreased from 50% in 1880 to 34% in 1900 and 4.9% in 1949 among those between 7 and 20 years of age. In 1949 illiteracy among persons between 16 and 20 had been reduced to about 1% (white, 0.5%; Negro, 2.0%).

A school code for Alabama was framed in 1919 as a result of a report of the results of an investigation made by the U.S. bureau of education at the request of a state educational commission. Extensive revisions of the code were made by the legislature in 1927. Further extensive studies of and reports on the state's educational system were made by the Brookings institution of Washington in 1932 and by a state commission in 1945.

In 1951 education was free between the ages of 6 and 20 and compulsory between the ages of 7 and 16. The school census of 1946 counted 784,922 children between the ages of 6 and 20. In 1948–49 the public schools enrolled 657,359, of whom 436,618 were in elementary grades and 220,741 in junior and senior high schools; 18,315 were enrolled in private and parochial schools. In 1948–49 there were 29,290 teachers in public elementary and secondary schools, of whom 20,064 were white and 9,226 Negro.



At mid-20th century the chief institutions of higher learning were: the University of Alabama, at Tuscaloosa; Alabama Polytechnic institute, at Auburn; Alabama college, at Montevallo; the state teachers' colleges at Florence, Jacksonville, Livingston and Troy; Athens college (Methodist, for women), at Athens; Birmingham-Southern college (Methodist), at Birmingham;

Howard college (Baptist), at Birmingham; Judson college (Baptist, for women), at Marion; Spring Hill college (Roman Catholic, for men), at Mobile; Huntingdon college (Methodist), at Montgomery; Talladega college (Congregationalist, for Negroes), at Talladega; Tuskegee institute (for Negroes), at Tuskegee; the Agricultural and Mechanical institute (for Negroes), at Normal; the State Teachers' college (for Negroes), at Montgomery; and Stillman college (for Negroes), at Tuscaloosa. Of junior college grade were St. Bernard college, Marion institute, and Snead junior college.

**Charities and Correction.**—Alabama's various philanthropic and penal institutions at mid-20th century included an institution for white deaf and blind and a school for Negro deaf and blind at Talladega; a hospital for insane whites and Negroes at Tuscaloosa and one for Negroes at Mount Vernon; a penitentiary; a state industrial school for white boys and a state training school for white girls, both near Birmingham; a reform school for juvenile Negroes at Mt. Meigs; and a school for mental defectives at Tuscaloosa, all these institutions being under the management of trustees appointed by the governor. The convict-lease system was abolished by the state legislature in 1927, after which convicts were largely employed by the state in highway construction and maintenance and in prison industries at Montgomery, Wetumpka, Speigner and Atmore. In 1901, a system of peonage that had grown up in the state attracted wide attention, and a federal grand jury at a single term of court indicted a number of men for holding persons as peons. Many similar cases were found later in other southern states, but those in Alabama, being the first discovered, attracted the most attention. The federal authorities took active measures to stamp out peonage and were supported by the press and by leading citizens of the state.

**Agriculture.**—Alabama is generally regarded as an agricultural state, but the rural farm population in 1940 was only 47.5% of the population. The number of farms in the state decreased from 262,901 in 1910 to 237,631 in 1925. After rising to 273,455 in 1935, the number declined again to 223,369 in 1945. The value of all crops, which was $56,872,944 in 1879, amounted to $304,348,638 in 1919, after which date it fell off steadily and stood at only $106,100,000 in 1935; it had risen again in 1945 to $298,295,633. In 1945 approximately 45% of the farms were managed by their owners, 6% by part owners, 17% by cash tenants and the remaining 32% by other tenants. Cotton has regularly been the chief agricultural product, though in some years the value of the corn (maize) crop has exceeded it. During the period 1911–15 the average annual cotton yield was 1,463,000 bales. From 1915–25 it was far below the 1,000,000 level, but it jumped for the period 1926–30 to 1,319,000. In 1935 the crop was 1,059,000 bales, but it had fallen in 1940 to 790,000 bales. The next time it exceeded 1,000,000 was in 1948, with 1,167,187 bales. In 1945 the corn harvest totalled 41,875,549 bu. with an approximate value of $65,000,000. The 1945 peanut crop of 328,470,099 lb. was valued at $24,627,328; the sweet potato crop, 5,900,148 bu. at $11,471,988; the hay crop, 486,981 tons at $9,414,368; the white potato crop, 2,896,264 bu. at $3,939,063.

**Minerals.**—An important feature of the industrial life of Alabama since 1880 has been the exploitation of its iron and coal resources. Bituminous coal, first mined near Tuscaloosa about 1827, was produced intensively after 1881; the output grew from 946 tons in 1840 and 13,200 tons in 1870 to 420,000 tons in 1881 and 1,568,000 tons in 1883. In 1923 the output reached 20,457,649 tons, with a value of $51,624,000 and then declined steadily until 1932, when the tonnage was 7,856,939 and the value $12,138,000. The output then rose to 18,800,954 tons, worth $116,626,000, in 1948. Most of this came from Jefferson and Walker counties, although coal underlies about 40% of the northern half of the state. It has been estimated that the total available coal resources of Alabama amount to almost 67,000,000,000 tons or enough for 7,500 years. The iron ore, primarily red hematite, is found chiefly in the region of which Birmingham is the centre. In 1905 Alabama produced 3,782,831 tons of iron ore; in 1923 there were shipped from the mines 6,922,663 tons valued at $15,540,198. Only 1,375,000 tons were mined in 1932, but by 1935 production had risen to 3,240,000 tons, and Alabama stood third among the ore-producing states of the union. Production in 1948 was 11,919,057 tons. Gold, silver, lead, copper, tin, graphite, and bauxite have also been produced. In 1948 Alabama produced minerals to the value of $182,987,000, ranking 16th among the states and producing 1.65% of the product of the whole union, coal, iron ore, cement and clay products being the chief mineral products of the state.

STEEL MILLS IN OPERATION AT BIRMINGHAM, ALABAMA

The coal formation, which underlies about 20% of the area of the State, is responsible for the development of the steel and iron mills that make Birmingham the chief industrial centre of the South

**Manufactures.**—The growth of manufactures in Alabama has been as remarkable as the revelation and exploitation of the state's mineral wealth. In 1880 the capital invested in manufactures was $9,668,008, little more than that of 1860; by 1890 it had increased to $46,122,571; in 1900 it amounted to $70,370,081, in 1919 to $455,592,733. On account of the proximity of coal, iron and limestone to each other, the manufacture of iron and steel, prior to the depression of the 1930s, was the most extensive in the state. The first blast furnace in Alabama was set up in 1818; from then until the Civil War numerous Catalan forges were in operation. In 1876 the first pig iron with coke for fuel was produced. In 1895 it was demonstrated that Alabama pig iron could be sent to Liverpool and sold more cheaply than the English product, and Birmingham (Alabama) came consequently to rank among the world centres of the pig iron trade. The pig iron produced in the state in 1860 was valued at $64,590, in 1900 at $13,487,769, in 1923 at $63,561,614, in 1933 at $10,047,165 and in 1948 at $145,358,582. Manufacture of steel and steel products began in 1888 but was not successful until the Duplex process was used. On account of the irregular quantities of iron and phosphorus present in Alabama ores, this special process, representing a combination of the Bessemer and open-hearth processes, is necessary. In 1923 Alabama ranked seventh among the states in steel production, with an output worth $75,042,823; however, the census of manufactures in 1933 failed to list it among the chief steel-producing states. In 1948 Alabama produced 4.9% of the steel made in the nation, having an annual capacity of 3,548,000 tons. To meet the demand from the iron and steel industries coke production rose to a value of $44,577,384 in 1923 and was $7,091,000 in 1933; in 1948 6,015,460 tons worth $57,611,881 were produced. In 1950 Alabama was the leading state in the production of cast-iron pipe.

A remarkable development of the cement industry occurred after 1910, made possible by the presence of almost inexhaustible deposits of limestone in the heart of rich coal fields, side by side with extensive areas of shale and clay in a territory served by adequate hydroelectric power. In 1924 the output was about 2,000,000 bbl., with a value of $2,645,000; in 1947 the product was 9,510,000 bbl., valued at $16,664,000.

The quantity of lumber and naval stores produced has been

notable. In 1923 the output of sawn lumber was valued at $52,792,121, of which yellow pine represented $46,289,706, oak $1,474,347, and poplar $1,307,823. The total value of lumber cut in 1933 was $14,222,244; in 1948 it was $303,900,000. In 1923, 131 turpentine and rosin factories turned out products valued at $2,809,815; in 1933 the product of 76 active factories was worth $1,661,682.

The manufacture of cotton goods, after a long period of early beginnings, developed rapidly from 1890, in which year there were only 13 cotton mills in the state, one more than in 1850; in 1900 there were 31, with an annual product valued at $8,153,136, representing an increase of 272% over the product ($2,190,771) of 1890; by 1923 there were 61 establishments, employing 20,785 people, with products valued at $86,384,724, and in 1933 there were 75 establishments with 28,762 workers and products worth $66,939,045. The product of all textile industries in the state in 1948 was valued at $485,500,000. During the 1940s the factories of the state consumed more raw cotton than the state produced.

In the 30 years from 1899 to 1929 the annual value added by manufacturing in Alabama increased from $34,112,000 to $258,125,000, but this had declined by 1933 to $113,470,000. In 1947 there were, on the average, 206,136 industrial employees in the state, who received $444,647,000 in salaries, the value added by manufacturing being $876,933,000.

Between 1910 and 1940 the manufacture of hydroelectric power became one of the state's most important industries. By 1950 three great dams had been built across the Coosa river, three across the Tallapoosa, and three across the Tennessee. In 1947 United States government plants and private plants at these dams had a capacity of 959,563 kw., at which time total electric-generating capacity in the state from all sources was 1,348,333 kw.

**Transportation.**—Alabama rivers are navigable for a total distance of some 2,000 mi., but obstructions sometimes prevent the use of a continuous route. The United States government spent millions of dollars on the elimination of these impediments and on the improvement of Mobile harbour. National, state and city funds were used to improve the facilities of the port of Mobile. During the closing months of 1920 the first vessel of a fleet of government-owned-and-operated self-propelled barges made its way down the Mississippi river to New Orleans and through the Mississippi sound to Mobile and then up the rivers to Birmingport and Cordova, in the heart of the Warrior coal fields, a system of locks and dams having canalized the Tombigbee and Warrior rivers, making the latter navigable deep into the mineral region of the Cumberland plateau. An amendment to the state constitution having authorized the use of the credit of the state for the purpose of constructing a great system of docks at Mobile, an act of the legislature at the session of 1923–24 provided for an issue of $10,000,000 of bonds for that purpose, and a special commission was put in charge of the work. The commission acquired for the state approximately 400 ac. of land with a water-frontage of two miles, on the northern outskirts of the city.

The port in 1951 had excellent docking facilities.

Railroads are the main carriers of the products of the mineral region. Here all the large systems of the southern states find an entrance: the Gulf, Mobile and Ohio, the Southern, the Louisville and Nashville, the St. Louis-San Francisco, the Illinois Central, the Seaboard Air Line, the Atlantic Coast Line, and the Central of Georgia forming connections with northern and Atlantic states. The total main-line mileage of railways in the state on Dec. 31, 1948, was 4,742 or 2.11% of the national total.

In 1950 there were 7,634 mi. of state highways, of which 7,119 mi. were paved; there were 52,579 mi. of county roads, of which 2,910 mi. were paved. In 1930 there were 277,146 motor vehicles registered; in 1949 the number was 540,265.

**"ALABAMA" ARBITRATION.** The facts of this case are as follows: In 1861 the southern states of North America seceded and set up a separate government. Hostilities began with the capture of Fort Sumter by the Confederates on April 13, 1861. On the 19th President Lincoln declared a blockade of the southern ports. On May 14 the British government issued a proclamation of neutrality, by which the Confederates were recognized as belligerents. This example was followed shortly afterwards by France and other states. In June 1862 the vessel, the "Alabama," originally known as "No. 290," was being built by Messrs. Laird at Birkenhead. She was then nearly completed and was obviously intended for a man-of-war. On June 23 Mr. C. F. Adams forwarded to Earl Russell a letter from the United States consul at Liverpool giving certain particulars as to her character. This letter was laid before the law officers, who advised that, if these particulars were correct, the vessel ought to be detained. On July 21 sworn evidence, which was supplemented on July 23, was obtained and laid before the commissioners of customs (who were the proper authorities to enforce the provisions of the Foreign Enlistment Act of 1819), but they declined to move. On July 23, the same evidence was laid before the law officers, who advised that there was sufficient ground for detention. By some accident, the papers were not returned till July 29. Instructions were then issued to seize the vessel, but she had already sailed on the evening of the 28th. Although she remained for two days off the coast of Anglesey, there was no serious attempt at pursuit. She afterwards made her way to the Azores, where she received her armament, which was brought from Liverpool in two British ships. Captain Semmes there took command of her under a commission from the Confederate government.

After a most destructive career she was sunk off Cherbourg by the "Kearsarge" on June 19, 1864.

On these facts the United States government alleged against Great Britain two grievances: first the recognition of the southern states as belligerents and a general manifestation of unfriendliness in other ways; second, the breach of neutrality in allowing the "Alabama," the "Florida," the "Shenandoah" and other Confederate vessels to be built and equipped on British territory.

Correspondence followed extending over several years and in 1871 a commission was appointed to determine the mode in which the questions at issue might be settled. The British commissioners suggested that the "Alabama" should be submitted to arbitration. The American commissioners refused "unless the principles which should govern the arbitrators in the considera-

tion of the facts could be first agreed." Eventually it was agreed that the three following rules should apply: A neutral government is bound—(1) to use due diligence to prevent the fitting out, arming or equipping within its jurisdiction of any vessel, which it has reasonable ground to believe is intended to cruise or to carry on war against a power with which it is at peace, and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessel having been specially adapted, in whole or in part, within such jurisdiction, to warlike use; (2) not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other, or for the purpose of the renewal, or augmentation of military supplies or arms or the recruitment of men; (3) to exercise due diligence in its own ports and waters and as to all persons within its jurisdiction to prevent any violation of the foregoing obligation and duties. These rules were embodied in the treaty of Washington (1871), which provided that the "Alabama" claims should be referred to a tribunal composed of five arbitrators, one to be named by each of the contracting parties and the remainder by three neutral powers. Art. 6 provided that the arbitrators should be governed by the three rules quoted above, and by such principles of international law not inconsistent therewith as the arbitrators should determine to be applicable to the case. By the same article the parties agreed to observe these rules as between themselves in future, and to bring them to the knowledge of other maritime powers. Art. 7 gave power to the arbitrators to award a sum in gross if Great Britain were adjudged in the wrong.

The treaty was, on the whole, welcomed in England. The United States appointed Mr. C. F. Adams as arbitrator and Mr. J. C. Bancroft Davis as agent. The British government appointed Sir Alexander Cockburn as arbitrator and Lord Tenterden as agent. The arbitrators appointed by the three neutral powers were Count Sclopis (Italy), M. Staempfli (Switzerland), Baron d'Itajuba (Brazil). The first meeting of the tribunal took place on Dec. 15, 1871, in Geneva. As soon as the cases had been formally presented, the tribunal adjourned till the following June. There followed immediately a controversy which threatened the collapse of the arbitration. The United States claimed damages not only for the property destroyed by the Confederate cruisers, but for such "indirect losses" as the transference of the American marine to the British flag, the enhanced payments of insurance, the expenses of pursuit and the prolongation of the war. They also revived the charges of "insincere neutrality" and "veiled hostility" which had figured in the diplomatic correspondence, and had been repudiated by Great Britain, and dwelt at length upon the premature recognition of belligerency, the unfriendly utterances of British politicians and the material assistance afforded to the Confederates by British traders. These claims for indirect losses, etc., caused great excitement in England. That they were within the treaty was disputed, and it was argued that, if they were, the treaty should be amended or denounced. In Oct. 1872 Lord Granville notified to General Schenck, the United States minister, that the British government did not consider that the indirect losses were within the submission, and in April the British counter-case was filed without prejudice to this contention. On June 15 the tribunal reassembled and the American argument was filed. To save the situation Mr. Adams persuaded his colleagues to make a spontaneous declaration that by the principles of international law the indirect claims ought to be excluded from their consideration. The discussion then turned mainly on the question of the measure of "due diligence." The United States contended that it must be a diligence commensurate with the emergency or with the magnitude of the results of negligence. The British government maintained that while the measure of care which a government is bound to use in such cases must be dependent more or less upon circumstances, it would be unreasonable to require that it should exceed that which the governments of civilized States were accustomed to employ in matters concerning their own security or that of their citizens.

The tribunal adopted the view suggested by the United States. It found that Great Britain was legally responsible for all the depredations of the "Alabama" and "Florida" and for those committed by the "Shenandoah" after she left Melbourne.

In the case of the "Alabama" the court was unanimous; in the case of the "Florida" Sir A. Cockburn alone, in that of the "Shenandoah" he and Baron d'Itajuba, dissented from the majority.

In the cases of the other vessels the judgment was in favour of Great Britain.

The tribunal decided to award a sum in gross, and (Sir A. Cockburn again dissenting) fixed the damages at $15,500,000 in gold.

On Sept. 14 the award was formally published, and signed by all the arbitrators except Sir A. Cockburn, who filed a lengthy statement of his reasons.

The first of the Washington Rules, with the substitution of the words "the means at its disposal" for the words "due diligence," was adopted by Art. 8 of the Hague Convention XIII., 1907.

*See* L. A. Atherley-Jones and H. H. L. Bellot, *Commerce in War* (1907). (H. H. L. B.)

**ALABAMA CITY,** formerly a city of Etowah county, Alabama, U.S.A., 60 mi. N.E. of Birmingham; it was annexed to Gadsden (*q.v.*) in 1932.

**ALABAMA RIVER,** a river of Alabama, U.S.A., formed by the Tallapoosa and Coosa rivers, which unite about 6 mi. above Montgomery.

It flows west as far as Selma, then south-west until, about 45 mi. from Mobile, it unites with the Tombigbee to form the Mobile and Tensas rivers, which discharge into Mobile bay.

The course of the Alabama is tortuous; its width varies from 600 to 900ft., depth from 3 to 7ft.; its length by the United States Survey is 312m.; by steamboat measurement, 420m. The river crosses the richest agricultural and timber districts of the State, and railways connect it with the mineral regions of north central Alabama. The principal tributary of the Alabama is the Cahaba (about 200m. long), which enters it about 10m. below Selma. Of the rivers which form the Alabama, the Coosa crosses the mineral region of Alabama, and is navigable for light-draft boats from Rome, Georgia (where it is formed by the junction of the Oostenaula and Etowah rivers), to about 117m. above Wetumpka (about 192m. below Rome and 26m. below Greensport), and from Wetumpka to its junction with the Tallapoosa; the channel of the river has been considerably improved by the Federal government. The navigation of the Tallapoosa river (which has its source in Paulding county, Ga., and is 250m. long) is prevented by shoals and a 60ft. fall at Tallassee, a few miles north of its junction with the Coosa. The Alabama, which is navigable throughout the year, is an important carrier of cotton, cotton seed, fertilizer, cereals, lumber and naval stores.

**ALABASTER** or **ARBLASTIER, WILLIAM** (1567–1640), English Latin poet and scholar, was born at Hadleigh, Suffolk, and was educated at Westminster school and Trinity college, Cambridge. Alabaster served with the expedition of Robert Devereux, earl of Essex, to Cadiz in 1596, and embraced the Roman Catholic faith while he was in Spain. He was imprisoned in the Tower for his religious opinions in 1598 and 1599. His mystical writings brought him into conflict with the Inquisition, and he was imprisoned in Rome for a short time. He escaped, returned to England, abjured Catholicism and received a prebend in St. Paul's Cathedral, which he held until his death in April 1640.

Alabaster's Latin tragedy, *Roxana,* written while he was at Cambridge, is modelled on *La Dalida* of Luigi Groto, and was first published in 1632. Samuel Johnson praised it as the only Latin verse worthy of note written in England before Milton's *Elegies.* One book of an epic poem in praise of Elizabeth, entitled *Elisaeis, apotheosis poetica,* is preserved at Emmanuel college, Cambridge. It was admired by Edmund Spenser. "Who lives that can match that heroic song?" he says in "*Colin Clout's come home againe.*" Other works by Alabaster are mystical in character and owe much to his study of the Kabbala. They include *Apparatus in revelationem Jesu Christi* (Antwerp, 1607), *Ecce*

*Sponsus venit* (1633), *Lexicon Pentaglotton* (1637) and mystical commentaries on Revelations and the Pentateuch.

*See* T. Fuller, *Worthies of England* (ii. 343); Pierre Bayle, *Dictionary, Historical and Critical* (1734); J. P. Collier, *Bibl. and Crit. Account of the Rarest Books in the English Language* (vol. i. 1865); also the *Athenaeum* (Dec. 26, 1903), where Mr. Bertram Dobell describes a ms. in his possession containing 43 sonnets by Alabaster.

**ALABASTER,** a name applied to two different mineral substances. The alabaster of the ancients is mostly a granular aggregate of crystals of calcium carbonate—*i.e.*, it is really a marble (*q.v.*). The alabaster of modern times is a granular form of the mineral gypsum (*q.v.*). It is usually white, pink or yellowish in colour, often with darker streaks and patches, and is very soft (hardness 1·5 to 2) so that it can be scratched by the finger nail. It can be readily distinguished from marble by the fact that it does not effervesce with acid. Alabaster is found in beds interstratified with red sandstones and marls deposited in the beds of salt lakes during an arid period: in England, chiefly in the Keuper marls of the midlands, especially at Chellaston in Derbyshire, Fauld in Staffordshire, and near Newark, Nottinghamshire, also in the neighbourhood of Carlisle, near Watchet in Somerset and Penarth in Glamorgan, all in the Trias.

On the Continent the centre of the alabaster trade is Florence, where it is found in Miocene and Pliocene strata, and is extensively used for statuary work and carving of ornamental objects. The best kind is pure white and translucent, but by careful heating in nearly boiling water it can be made nearly opaque, resembling marble. This appears to be due to partial dehydration.

(R. H. Ra.)

**ALABASTROS** or **ALABASTOS,** a Greek vase, shaped like an urn. The most common type of the alabastros stands on a base that balances, in appearance, its rather wide mouth. (*See* Pottery and Porcelain: *Greek Pottery.*)

**ALACALUF,** an Indian tribe, almost extinct, living in the west Patagonian channels, chiefly in the vicinity of Ración sound. Formerly they were much more numerous, and their canoes might be seen southward from the Gulf of Peñas to Brecknock peninsula in Tierra del Fuego, including the Straits of Magellan. Their culture in general closely resembles that of the other canoe-using tribe of Tierra del Fuego, the Yahgan (*q.v.*). The use of planked canoes by the Alacaluf has suggested the possibility of culture transference from Polynesia, but the Alacaluf planked canoe is demonstrably a local development.

*See* J. M. Cooper, "Analytical and Critical Bibliography . . . of Tierra del Fuego," in *Bureau of American Ethnology Bulletin 63* (1917). (S. K. L.)

**ALACOQUE** or **AL COQ, MARGUERITE MARIE** (1647–1690), French nun and founder of the devotion to the Sacred Heart of Jesus, was born at Lauthecourt on July 22, 1647, and died on Oct. 17, 1690. Having been cured of paralysis, as she believed by the intercession of the Blessed Virgin, in 1671 she entered the Visitation convent at Paray-le-Monial and in the following year made her final vows. After a long period of severe austerities she testified that Christ had revealed to her His heart burning with love for man, and bade her establish the Holy Hour, communion on the first Friday of the month and the feast of the Sacred Heart to be observed on the Friday after the octave of Corpus Christi. The devotion to the Sacred Heart spread rapidly throughout Christendom, and Marguerite Marie was pronounced venerable in 1824, blessed in 1864, and finally on May 13, 1920, was canonized.

Her writings and autobiography are contained in *Vie et Oeuvres par les Contemporaines,* 2 vols. (Paris, 1901), her autobiography being published again at Paray-le-Monial in 1918. *See* also E. Bougaud, *Life of St. Margaret Mary Alacoque* (New York, 1920).

**ALAGOAS,** a maritime state of Brazil, bounded north and west by the State of Pernambuco, south and west by the State of Sergipe, and east by the Atlantic. It has an area of 11,031 square miles. A dry, semi-barren plateau, fit for grazing only, extends across the western part of the State, breaking down into long fertile valleys and wooded ridges towards the coast, giving the country a mountainous character. The coastal plain is filled with lakes (*lagoas*), in some cases formed by the blocking up of river outlets by beach sands. The valleys and slopes are highly fertile and produce sugar, cotton, tobacco, Indian corn, rice, mandioca and fruits. Hides and skins, mangabeira rubber, cabinet woods, castor beans and rum are also exported. Cattle-raising was formerly a prominent industry, but it has greatly declined. Manufactures were developed to a limited extent only, though protective tariff laws were adopted for their encouragement. The climate is hot and humid, and fevers are prevalent in the hot season. The capital, Maceió (pop. 124,544), is the chief commercial city of the state, and its port (Jaraguá) has a large foreign and coastwide trade. The principal towns are Alagoas, formerly the capital, picturesquely situated on Lake Manguaba, 15 mi. southwest of Maceió, Palmeira dos Indios (pop. 67,202) and Santana do Ipanema (pop. 61,456). Before 1817 Alagoas formed part of the *capitania* of Pernambuco, but in that year the district was rewarded with a separate government and in 1823 became a province of the empire. The advent of the republic in 1889 changed the province into a state. Pop. (1950) 1,106,454.

**ALAIN DE LILLE** (Alanus de Insulis) (*c.* 1128–1202), French theologian and Latinist, lived at Montpellier, and finally retired to the Abbey of Citeaux, where he remained until his death. His varied learning won for him the title of *Doctor universalis.* He was famed in his day for two of his Latin poems, *De planctu naturae,* a satire on human vices, and *Anticlaudianus,* a long verse treatise on the arts and on morals. Alain shared in the reaction against scholasticism, and laid stress on the share of faith in the apprehension of religious truth. He must be classed with the so-called Summists. But his *De arte seu de articulis catholicae fidei,* which was a "summa" of Christian theology, brings the principles of mathematical science to bear on Christian dogma. He also wrote a treatise *contra haereticos.*

The works of Alain de Lille have been published by Migne, *Patrologia latina,* vol. ccx. A critical edition of the *Anticlaudianus* and of the *De planctu naturae* is given by Th. Wright in vol. ii. of the *Anglo-Latin Satirical Poets and Epigrammatists of the Twelfth Century* (London, 1872). *See* Hauréau, *Mémoire sur la vie et quelques oeuvres d'Alain de Lille* (Paris, 1885); M. Baumgartner, *Die Philosophie des Alanus de Insulis* (Münster, 1896).

**ALAIS:** *see* Alès.

**ALAJUELA,** a province of Costa Rica, Central America, extending southward from the border of Nicaragua to the Meseta Central: area, 3,653 sq.mi.; pop. (1940), 137,943. The capital of the province (Alajuela), served by the Pan American highway and a branch line of the coast-to-coast railway, is in the highly productive and populous central valley: elev., 3,185 ft.; mean annual temp., 68° F.; pop. (1940), 9,232.

The province is predominantly agricultural in its economy, producing large quantities of sugar cane, coffee, cereals, fruits, subsistence crops and cattle.

**ALAMANNI** or **ALLEMANNI,** a German people first mentioned by Dio Cassius. They dwelt in the basin of the Maine, to the south of the Chatti (*q.v.*). They were a conglomeration of various tribes. The Hermunduri formed the preponderating element, and there were among the others the Iuthungi, Bucinobantes and Lentienses. From the 4th century A.D. onwards we hear also of the Suebi (*q.v.*) or Suabi. The Hermunduri belonged to the Suebi, but reinforcements from new Suebic tribes now moved westward. In later times the names Alamanni and Suebi seem to be synonymous. They were continually engaged in conflicts with the Romans, the most famous encounter being that at Strassburg, in which they were defeated by Julian (A.D. 357). Early in the 5th century the Alamanni crossed the Rhine and conquered and settled Alsace and a large part of Switzerland. In A.D. 495 they were conquered by Clovis, from which time they formed part of the Frankish dominions. The Alamannic and Swabian dialects survive in Swiss dialects, and in parts of South Germany, particularly Baden and Württemburg and also parts of Alsace.

**ALAMANNI** or **ALEMANNI, LUIGI** (1495–1556), Italian statesman and poet, was born at Florence. Luigi joined with others in an unsuccessful conspiracy against Giulio de' Medici, afterwards Pope Clement VII. He was obliged to take refuge in Venice, and, on the accession of Clement, to flee to France. When Florence shook off the papal yoke in 1527, Alamanni returned, and took a prominent part in the management of the affairs of the republic. On the restoration of the Medici in 1530 he had again to take refuge in France, where he enjoyed the favour both of Francis I and Henry II. He died at Amboise on April 18, 1556. His best work, *La Coltivazione* (Paris, 1546), is a didactic poem, written in imitation of Virgil's *Georgics*. His *Opere Toscane* (Lyons, 1532) consists of satirical pieces written in blank verse. An unfinished poem, *Avarchide*, in imitation of the *Iliad*, was the work of his old age and has little merit. It has been said by some that Alamanni was the first to use blank verse in Italian poetry, but the distinction belongs rather to his contemporary Giangiorgio Trissino. He also wrote a poetical romance, *Girone il Cortese* (Paris, 1548); a tragedy, *Antigone;* a comedy, *Flora,* and other poems. His works were published, with a biography, by P. Raffaelli, as *Versi e prose di Luigi Alamanni* (Florence, 1859).

BIBLIOGRAPHY.—G. Naro, *Luigi Alamanni e la coltivazione* (Syracuse, 1897), and C. Corso, *Un decennio di patriottismo di Luigi Alamanni* (Palermo, 1898).

**ALAMBAGH,** the name of a large park or walled enclosure, containing the ruins of a country house of the old Oudh court, as well as a beautiful garden, situated about 4m. from Lucknow, near the Cawnpore road, in the United Provinces of India. It was converted into a fort by the mutineers in 1857, and after its capture by the British was of importance in connection with the military operations around Lucknow. Sir Henry Havelock was buried in the garden.

**ALAMEDA,** a city of Alameda county, California, U.S.A., an island approximately 1 mi. wide and 5½ mi. long, at the eastern or mainland side of San Francisco bay, 12 mi. E. of the city of San Francisco. One entire side, 5½ mi. in length, faces on a deepwater channel and is used largely as a commercial waterfront. The city of Alameda is connected by the Posey tube and four bridges with its neighbouring cities, including the city of Oakland, and thence with the San Francisco Bay bridge. Pop. (1950) 63,425; (1940) 36,256.

Although largely residential, Alameda is important for its shipbuilding yards and ship-repair and dry-dock facilities. The city has both heavy and light industrial plants, including food and candy factories. Shipping terminals and warehouses have direct access to water and rail facilities and barge and trucking services. There are large plants for oil storage and distribution.

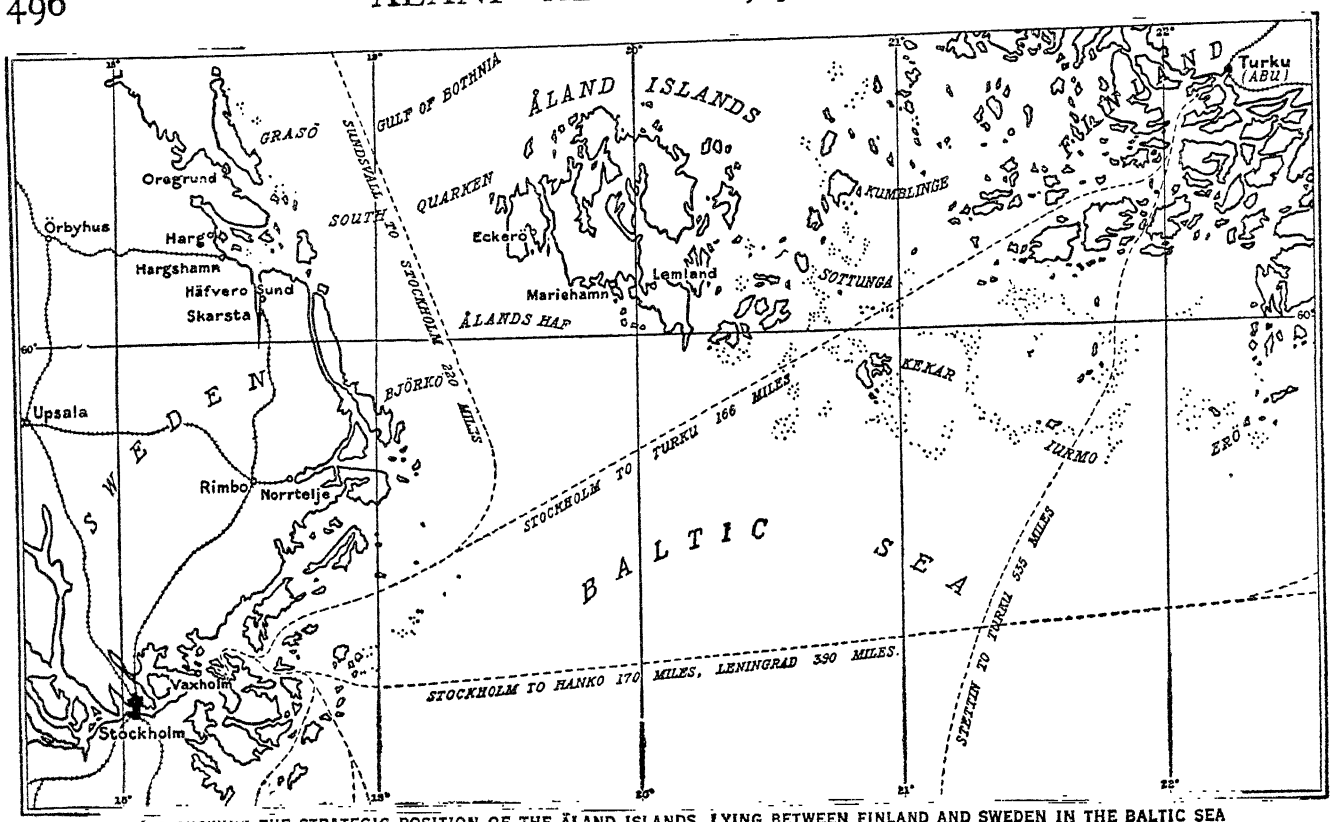
Alameda is the site of a U.S. naval air station, a maritime commission training school, a coast guard base and an army depot. The city was incorporated in 1854 and in 1917 adopted a city-manager form of government with five councilmen elected by the people. It owns and operates its own electric distributing plant and a golf course. There are swimming and fishing facilities and a yacht harbour and boat clubs facing out on the surrounding waters. Gross assessed valuation in 1950 was $43,458,610.

**ALAMO, THE,** historic building in San Antonio, Tex., noted as the scene of a heroic defense in the war between Texas and Mexico. This building is the chapel of the Mission San Antonio de Valero, founded in 1718 by Franciscans, and commonly called the "Alamo mission" from the grove of cottonwood (*alamo*) in which it stood. It originally consisted of the chapel, a convent yard about 100 ft. square, a convent and hospital building and a plaza about 2½ ac. in extent, the whole being surrounded by a strong wall. Upon the disappearance of the Indians from the vicinity the mission was abandoned, and after 1793 it was sometimes used as a fort. In the war for Texan independence Cols. William B. Travis, James Bowie and Davy Crockett, with 180 men, were attacked there by 4,000 Mexicans commanded by Antonio Lopez de Santa Anna. After a siege lasting 13 days, Feb. 23–March 6, 1836, during which about 500 of the attacking force were killed, a breach was made in the walls. In a final assault the Mexicans overpowered and slaughtered the garrison in a hand-to-hand struggle in the chapel, the five survivors being subsequently killed in cold blood by order of Santa Anna. "Remember the Alamo" became the war cry of the Texans who, under Sam Houston, at San Jacinto, on April 21, 1836, defeated and captured Santa Anna. In 1883 the Alamo building was bought by the state and preserved as a public monument, and in 1913 the city of San Antonio began its restoration.

*See* A. M. Williams, *Sam Houston and the War of Independence in Texas* (1893); Zavola, *Story of the Siege and Fall of the Alamo* (1911).

**ALAMOS DE BARRIENTOS, BALTASAR** (1555–1640), Spanish scholar, was born at Medina del Campo in 1555. His friendship with Antonio Pérez (*q.v.*) caused him to be arrested in 1590 and imprisoned for nearly 13 years. His *Tácito español ilustrado con aforismos* (Madrid, 1614) is the only work which bears his name, but he is probably author of the *Discurso del gobierno* ascribed to Pérez. Through the influence of Pedro de Lerma and Gaspar Olivares (*q.v.*) he later attained high position.

**ÅLAND ISLANDS,** an archipelago at the entrance to the Gulf of Bothnia, about 25 mi. from the coast of Sweden, and 15 mi. from that of Finland. Area 572 sq.mi., with a population of 21,196 (1940). The group which forms the Finnish department of Åland (Ahvenanmaa), consists of nearly 300 islands, of which about 80 are inhabited, the remainder being desolate rocks. These islands form a continuation of a dangerous granite reef extending along the south coast of Finland. They formerly belonged to Sweden, and in the neighbourhood the first victory of the Russian fleet over the Swedes was gained by Peter the Great in 1714. They were ceded to Russia in 1809, and remained Russian until 1917, when Finland was proclaimed an independent and sovereign state. The population centres chiefly in the island of Åland, upon which is the small town Mariehamn. The inhabitants, hardy seamen and fishermen, are mostly of Swedish descent and speech. The surface of the islands is generally sandy, the soil thin and the climate keen; yet Scotch fir, spruce and birch are grown; and rye, barley, flax and vegetables are produced. Great numbers of cattle are reared; and cheese, butter and hides, as well as salted meat and fish, are exported. There are several excellent harbours (notably that of Ytternäs), which were of great importance to Russia from the fact that they are frozen up for a much briefer period than those on the coast of Finland.



**History.**—When, by an article of the Treaty of Fredrikshavn (Friedrichshamn), Sept. 5–17, 1809, the islands were ceded to Russia, together with the territories forming the grand-duchy of Finland on the mainland, the Swedes were unable to secure a provision that the islands, occupying a position of great strategic importance in relation to the entrance to Stockholm and to the Gulf of Bothnia, should not be fortified. The question was a vital one for Great Britain's trade as well. In 1854, accordingly, during the Crimean War, an Anglo-French force destroyed the fortress of Bomarsund. By the "Åland Convention," between Great Britain, France and Russia on March 30, 1856, it was stipulated that "the Åland islands shall not be fortified, and that no military or naval establishments shall be maintained or created on them."

By the 33rd article of the Treaty of Paris (1856) this convention, annexed to the final act, was given "the same force and validity as if it formed part thereof."

In 1906 it was asserted that Russia, under pretext of stopping the smuggling of arms into Finland, was massing considerable forces at the islands.

The question of the Åland islands created discussion in 1907 and 1908 in connection with the new North sea agreements, but Russia did not raise the issue officially when she saw the aversion of the other powers even to discuss it.

Under the tsardom the islands were united with Finland until the latter country declared her independence in 1917. In Dec. 1917, the Åland islanders claimed the right of self-determination on their own account, and unofficial plebiscites showed a vote in favour of reunion with Sweden. Finland granted the islands autonomy on May 7, 1920, but refused to contemplate their secession. In June the leaders of the secession movement were

**MAP SHOWING THE STRATEGIC POSITION OF THE ÅLAND ISLANDS, LYING BETWEEN FINLAND AND SWEDEN IN THE BALTIC SEA**

The Åland Islands, a self governing group within the Finnish body politic, were guarded by Russia for over a century because of their strategic position in the Baltic sea. They acquired the right of self determination after the World War (1914–18) and were guaranteed neutralization by the Baltic powers. The majority of the inhabitants are Swedish

arrested for high treason, and Finnish troops were sent to the island. As this situation was producing a state of serious tension between Finland and Sweden, Great Britain drew the attention of the Council of the League of Nations to the movement on June 19, 1920.

With the consent of the two interested governments, the Council asked a special commission of jurists whether the question was international or the exclusive concern of Finland. This commission declared the question international, whereupon the Council despatched a special commission of inquiry to the spot. This commission reported against the claim of the islanders to secede from Finland, but declared that the islanders formed a distinct group within the Finnish body politic, and suggested that the maintenance of Finnish sovereignty ought to be made conditional upon the incorporation in the autonomy law of May 7, 1920, of five specific guarantees. The commission also reported in favour of a new convention, to be signed by all the Baltic powers, for the neutralization and demilitarization of the Åland Islands, to replace the international convention of March 30, 1856. This report was accepted by the Council and the two nations. The new neutralization convention came into effect April 6, 1922. After much discussion Finland and Sweden agreed upon strengthening the defenses of the islands (Jan. 1939); the other interested states agreed except for Russia, whose protest postponed action. At the end of the same year Russia invaded Finland. In the peace agreement of March 1940, Russia demanded no concessions in the Åland Islands.

**ALANI,** eastern division of the Sarmatians, half-caste Scyths, a wandering people resembling Mongols. First met with north of the Caspian, then (*c.* 1st century A.D.) spreading into the steppes of Russia, the Alani made incursions into both the Danubian and the Caucasian provinces of the Roman empire. By the Huns they were cut into two portions, of which the western joined the Germanic nations in their invasion of southern Europe, and, following the fortunes of the Vandals, disappeared in North Africa. Those of the eastern division, though dispersed about the steppes until late mediaeval times, were forced by fresh invading hordes into the Caucasus, where they remain as the Ossetes. (*See* SARMATAE and SCYTHIA.)

**ALANINE,** *α Alanine*, is a constituent, and decomposition product, of many proteins, soluble in water or alcohol, crystallizing in colourless, sharp rhombic prisms, and having marked physiological action.

It has the formula of *α* amino-proprionic acid, $NH_2{\cdot}CHMe{\cdot}CO_2H$, and exists in the *d*-, *l*- and *r*-isomeric forms (*see* ISOMERISM).

**ALAPAEVSK,** a town in Sverdlovsk region of Russian S.F.S.R. Pop. 12,151. Lat. 57° 49′ N. Long., 61° 40′ E. It was known for its copper as long ago as 1704, and is in the copper and iron mining area. Since it was linked by rail with Sverdlovsk and Nizhni-Tagil, its importance has greatly increased.

**ALARCON, HERNANDO DE,** Spanish navigator of the 16th century, was sent by the viceroy of New Spain in 1540 to give naval support to the expedition of Francisco Vasquez de Coronado in his search for the mythical seven cities of Mexico. The junction was never effected. Alarcon sailed up the Gulf of California, and determined with certainty that California was a peninsula, not an island.

He surveyed the coast, ascended the Rio del Tizon or Rio de Buena Guia (Colorado) for 85 Spanish miles and planted a cross at the highest point he reached.

Under the cross he buried a note afterwards found by Melchior Diaz.

*See* Herrera, Decade VI. book ix. ch. 15; vol. vi. fol. 212 of Madrid edition of 1730, and the report printed in Hakluyt's voyages.

**ALARCON, JUAN RUIZ DE** (*c.* 1581–1639), Spanish dramatist, was born about 1581 at Tlacho (Mexico), where his father was superintendent of mines, and died at Cordova on Aug. 4, 1639. Alarcon was educated in Spain, then, after a brief stay in

Mexico, returned to Spain and occupied a small post under the Council of the Indies. His plays were published in 1628 and 1634; the most famous of these is *La Verdad sospechosa,* which was adapted by Corneille as the *Menteur.* Alarcon was preoccupied with ethical aims, and his gift of dramatic presentation was as brilliant as his dialogue was natural and vivacious. It has been alleged that his foreign origin is noticeable in his plays, but in *El Tejedor de Segovia* he had produced a masterpiece of national art, national sentiment and national expression.

**ALARCON, PEDRO ANTONIO** (1833–1891), Spanish writer, was born at Guadix March 10 1833. He had a considerable reputation as a journalist and poet when his play, *El Hijo pródigo,* was hissed off the stage in 1857. The failure exasperated Alarcon so much that he enlisted under O'Donnell as a volunteer in the Moroccan campaign. The expedition provided the material for the brilliant *Diario de un testigo de la guerra de Africa* (1859), a masterpiece in its way as a description of campaigning life. On his return from Morocco, Alarcon did great service to the liberal cause as editor of *La Politica.* But in the years 1868–74 he ruined his political reputation by a series of rapid changes of front. His literary reputation steadily increased, however. *El sombrero de tres picos* (1874), a clever resetting of an old Spanish tale, lives for its malicious wit and minute observation. His other works include *Cuentos amatorios* (1881); *Historietas nacionales* (1881); *El Escandalo* (1875); *El Capitan Veneno* (1881). Alarcon died July 20, 1891.

**ALARD, JEAN DELPHIN** (1815–1888), famous French violinist and teacher, was professor at the Paris Conservatoire from 1843 to 1875. Sarasate was one of his pupils.

**ALARIC** (*c.* 370–410), Gothic conqueror, the first Teutonic leader who stood as a conqueror in the city of Rome, was probably born about 370 on an island named Peucè (the fir) at the mouth of the Danube. He was of noble descent, his father being a scion of the family of the Balthi or Bold-men, next in dignity among Gothic warriors to the Amals. He was a Goth and belonged to the western branch of that nation (sometimes called the Visigoths) who at the time of his birth were quartered in the region now known as Bulgaria, having taken refuge on the southern shore of the Danube from the pursuit of their enemies the Huns.

In the year 394 he served as a general of *foederati* (Gothic irregulars) under the Emperor Theodosius in the campaign in which he crushed the usurper Eugenius. As the battle which terminated this campaign, the battle of the Frigidus, was fought near the passes of the Julian Alps, Alaric probably learnt at this time the weakness of the natural defences of Italy on her north-eastern frontier.

In the shifting of offices which took place at the beginning of the reigns of Arcadius and Honorius, the sons of Theodosius, Alaric apparently hoped that he would receive one of the great war ministries of the empire, and thus instead of being a mere commander of irregulars would have under his orders a large part of the imperial legions. This, however, was denied him, and he remained an officer of *foederati.* His disappointed ambition prompted him to take the step for which his countrymen were longing, for they too were grumbling at the withdrawal of the "presents," in other words the veiled ransom-money, which for many years they had been accustomed to receive. They raised him on a shield and acclaimed him as a king; leader and followers both resolved (says Jordanes, the Gothic historian) "rather to seek new kingdoms by their own labour, than to slumber in peaceful subjection to the rule of others."

Alaric struck first at the eastern empire. He marched to the neighbourhood of Constantinople, but finding himself unable to undertake the siege of the city, he retraced his steps westward and marched southward through Thessaly and the unguarded pass of Thermopylae into Greece. Alaric's invasion of Greece lasted two years (395–96); he ravaged Attica but spared Athens, which at once capitulated to the conqueror, and penetrated into Peloponnesus, capturing its most famous cities, Corinth, Argos and Sparta, selling many of their inhabitants into slavery. Here, however, his victorious career ended. Stilicho, who had come a second time to the assistance of Arcadius, succeeded in shutting up the Goths in the mountains of Pholoe on the borders of Elis and Arcadia. Alaric escaped with difficulty, and not without some suspicion of connivance on the part of Stilicho. He crossed the Corinthian gulf and marched with the plunder of Greece northwards to Epirus.

Next came an astounding transformation. For some mysterious reason, probably connected with the increasing estrangement between the two sections of the empire, the ministers of Arcadius conferred upon Alaric the government of part of the important prefecture of Illyricum. Here, ruling the Danubian provinces, he was on the confines of the two empires, and, in the words of the poet Claudian, he "sold his alternate oaths to either throne," and made the imperial arsenals prepare the weapons with which to arm his Gothic followers for the next campaign. It was probably in the year 400 that Alaric made his first invasion of Italy, co-operating with another Gothic chieftain named Radagaisus. After spreading desolation through north Italy, and striking terror into the citizens of Rome, Alaric was met by Stilicho at Pollentia (a Roman municipality in what is now Piedmont). The battle (April 6, 402, Easter day) was a victory, though a costly one, for Rome and effectually barred the further progress of the barbarians. Alaric was an Arian Christian who trusted to the sanctity of Easter for immunity from attack, and the enemies of Stilicho reproached him for having gained his victory by taking an unfair advantage of the great Christian festival. The wife of Alaric is said to have been taken prisoner after this battle; and there is some reason to suppose that he was hampered in his movements by the presence with his forces of large numbers of women and children, having given to his invasion of Italy the character of a national migration. After another defeat before Verona, Alaric quitted Italy, probably in 403.

He had not indeed reached Rome, but his invasion of Italy had produced important results. It had caused the imperial residence to be transferred from Milan to Ravenna, it had necessitated the withdrawal of the 20th legion from Britain, and it had probably facilitated the great invasion of Vandals, Suevi, and Alani into Gaul, by which that province and Spain were lost to the empire. We next hear of Alaric as the friend and ally of his late opponent Stilicho. The estrangement between the eastern and western courts had in 407 become so bitter as to threaten civil war, and Stilicho was actually proposing to use the arms of Alaric in order to enforce the claims of Honorius to the prefecture of Illyricum. The death of Arcadius in May 408 caused milder counsels to prevail in the western cabinet, but Alaric, who had actually entered Epirus, demanded that if he were thus suddenly bidden to desist from war, he should be paid handsomely for what in modern language would be called the expenses of mobilization. The sum which he named was a large one. 4,000 pounds of gold (about £160,000 sterling), but under strong pressure from Stilicho the Roman senate consented to promise its payment.

Three months later Stilicho himself and the chief ministers of his party were treacherously slain in pursuance of an order extracted from the timid and jealous Honorius; and in the disturbances which followed the wives and children of the barbarian *foederati* throughout Italy were slain. The natural consequence was that these men to the number of 30,000 flocked to the camp of Alaric, clamouring to be led against their cowardly enemies. He accordingly crossed the Julian Alps, and in Sept. 408 stood before the walls of Rome (now with no capable general like Stilicho to defend her) and began a strict blockade.

No blood was shed this time; hunger was the weapon on which Alaric relied. When the ambassadors of the senate in treating for peace tried to terrify him with their hints of what the despairing citizens might accomplish, he gave with a laugh his celebrated answer, "The thicker the hay, the easier mowed!" After much bargaining, the famine-stricken citizens agreed to pay a ransom of more than a quarter of a million sterling, besides precious garments of silk and leather and three thousand pounds of pepper. Thus ended Alaric's first siege of Rome. At this time, and indeed throughout his career, the one dominant idea of Alaric was not to pull down the fabric of the empire but to secure for himself, by negotiation with its rulers, a regular and recognized position within its borders. His demands were certainly large—the concession of

a block of territory 200 m. long by 150 wide between the Danube and the Gulf of Venice (to be held probably on some terms of nominal dependence on the empire), and the title of commander-in-chief of the imperial army. As all attempts to conduct a satisfactory negotiation with this emperor failed, Alaric, after instituting a second siege and blockade of Rome in 409, came to terms with the senate, and with their consent set up a rival emperor and invested the prefect of the city, a Greek named Attalus, with the diadem and the purple robe. But Attalus rejected the advice of Alaric and lost in consequence the province of Africa, the granary of Rome, which was defended by the partisans of Honorius. The weapon of famine, formerly in the hand of Alaric, was thus turned against him, and loud in consequence were the murmurs of the Roman populace. Honorius was also greatly strengthened by the arrival of six legions sent from Constantinople to his assistance by his nephew Theodosius II. Alaric therefore cashiered his puppet emperor Attalus after 11 months of ineffectual rule, and once more tried to reopen negotiations with Honorius. These negotiations would probably have succeeded but for the malign influence of another Goth, Sarus, the hereditary enemy of Alaric and his house. When Alaric found himself once more outwitted, he marched southward and began in deadly earnest his third siege of Rome. No defence apparently was possible; there are hints, not well substantiated, of treachery; there is greater probability of surprise. However this may be (for our information at this point of the story is miserably meagre) on Aug. 24, 410, Alaric and his Goths burst in by the Salarian Gate on the north-east of the city. The Goths showed themselves not absolutely ruthless conquerors, and there is no reason to attribute any extensive destruction of the buildings of the city to Alaric and his army. Contemporary ecclesiastics recorded with wonder many instances of their clemency: the Christian churches saved from ravage; protection granted to vast multitudes both of pagans and Christians who took refuge therein; vessels of gold and silver, which were found in a private dwelling, spared because they "belonged to St. Peter"; at least one case in which a beautiful Roman matron appealed, not in vain, to the better feelings of the Gothic soldier who had assailed her.

Alaric then marched southwards into Calabria. He desired to invade Africa, which on account of its corn crops was now the key of the position; but his ships were dashed to pieces by a storm in which many of his soldiers perished. He died soon after, probably of fever, and his body was buried under the river-bed of the Busento, the stream being temporarily turned aside from its course while the grave was dug wherein the Gothic chief and some of his most precious spoils were interred. When the work was finished the river was turned back into its usual channel, and the captives by whose hands the labour had been accomplished were put to death that none might learn their secret. He was succeeded in the command of the Gothic army by his brother-in-law, Ataulphus.

Our chief authorities for the career of Alaric are the historian Orosius and the poet Claudian, both strictly contemporary; Zosimus, a somewhat prejudiced heathen historian, who lived probably about half a century after the death of Alaric; and Jordanes, a Goth who wrote the history of his nation in the year 551, basing his work on the earlier history of Cassiodorus (now lost), which was written *c.* 520.

(T. H.; X.)

**ALARIC II.** (d. 507), eighth king of the Goths in Spain, succeeded his father Euric, or Evaric, on Dec. 28, 484. His dominions not only included the whole of Spain except its north-western corner, but also Aquitaine and the greater part of Provence. In religion Alaric was an Arian, but he greatly mitigated the persecuting policy of his father, Euric, towards the Catholics and authorized them to hold, in 506, the council of Agde. He appointed a commission to prepare an abstract of the Roman laws and imperial decrees, which should form the authoritative code for his Roman subjects. This is generally known as the *Breviarium Alaricianum*, or *Breviary of Alaric* (*q.v.*). Alaric endeavoured strictly to maintain the treaty which his father had concluded with the Franks, but Clovis found a pretext for war in the Arianism of Alaric. The two armies met in 507 at the Campus Vogladensis, near Poitiers, where the Goths were defeated, and their king, who took to flight, was overtaken and slain, it is said, by Clovis himself. This battle ended the rule of the Visigoths in Gaul.

**ALA-SHEHR** (anc. PHILADELPHIA), Aidin vilayet, Turkey. in the Kuzu Chai valley (*Cogamus*), at the foot of the Boz Dagh (Mt. Tmolus) 83 mi. east of Smyrna (105 by railway). Population 32,801. Philadelphia was founded by Attalus II. of Pergamum about 150 B.C., became one of the "Seven Churches" of Asia, and was called "Little Athens" on account of its festivals and temples. It was subject to frequent earthquakes. Philadelphia was an independent neutral city, under the Latin Knights of Rhodes, when taken in 1390 by Sultan Bayezid I. and an auxiliary Christian force under the emperor, Manuel II., after a long resistance, when all other cities of Asia Minor had surrendered. Twelve years later it was captured by Timur, who built a wall with the corpses of his prisoners. A fragment of the ghastly structure is in the library of Lincoln cathedral. The town is connected by railway with Afiun Qarahisar and Smyrna. It is ill-built, but, as it stands above the wide fertile Hermus plain, the distant view is imposing. There are small industries and a fair trade. A mineral spring yields a heavily charged water, "Eau de Vals," in great request in Smyrna.

*See* W. M. Ramsay, *Letters to the Seven Churches* (1904).

**ALAS, LEOPOLDO** (1852–1901), Spanish novelist and critic, was born at Zamora. His reputation rests on his psychological novel, *La Regenta* (1884–85), whose scene is laid in Oviedo. The ruthless analysis of its characters gives it a place among the best novels of the period.

**ALASKA,** once called Russian America, is a territory of the United States of America, occupying the extreme northwestern part of North America and including the adjacent islands. The name "Alaska", an adaptation of the Aleut "A-la-as-ka," means "the great country." The territory of Alaska comprises first, all that part of the continent west of the 141st meridian; secondly, the eastern Diomede Island in Bering strait, and all islands in Bering sea and the Aleutian chain lying east of a line drawn from the Diomedes to pass midway between Copper Island, off Kamchatka, and Attu Island of the Aleutians; thirdly, a narrow strip of coast and adjacent islands north of a line drawn from Cape Muzon, in latitude 54° 40′ N., up Portland canal to its head, and thence, following the summit of the mountains situated parallel to the coast to the 141st meridian, provided that when the line runs more than ten marine leagues from the ocean the limit shall be formed by a line parallel to the windings of the coast and which shall never exceed the distance of ten marine leagues therefrom. Alaska is bounded on the north by the Arctic ocean, on the west by the Arctic ocean, Bering sea and Bering strait, on the south and southwest by the Gulf of Alaska and the Pacific ocean, and on the east by British Columbia and Yukon territory. The total area of Alaska is 586,400 sq.mi., an area equal to nearly one-fifth that of continental United States or more than twice the size of Texas, the largest state of the union.

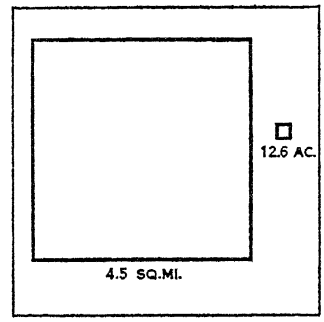
A RAVEN TOTEM POLE

Totem poles are erected by the Alaskan Indians to the animal from which they think their tribe has descended

**Principal Physical Features.**—As indicated by the above boundaries, Alaska is of straggling, irregular shape, extending in longitude from about 130° W. to 193° W. or 167° E., as specified in the articles of cession and through more than 20° of latitude, 51° to 71° 25′ N. The southern limit lies far out in the Pacific as part of the Aleutian island chain, only 2° north of the boundary between the western half of the United States and Canada. Alaska consists of a compact central mass and two straggling appendages running from its southwestern and southeastern corners. These three parts will be referred to hereafter respectively, as continental Alaska, Aleutian Alaska and the "Panhandle."

The general ocean coast line is about 4,750 mi. and including the islands, bays, inlets and rivers to the head of tide water, is about



26,000 mi. in length. The entire southern coast is very precipitous, much indented by deep fiords, with only slight stretches of beach or plain. Its elevation gradually decreases as one travels west toward the Aleutians.

A great submarine platform extends throughout a large part of Bering sea. The western and northern coasts are regular in outline, with long straight beaches, and shallows are common in the seas that wash them.

Of the vast number of islands within the boundaries of Alaska and constituting part of its territory, only a few of the more important can be mentioned in an article of this scope. At the southeastern extremity and lying close inland is the Alexander archipelago (*q.v.*) consisting of about 1,100 islands, large and small. Southwest of the Alaska peninsula there are two groups: (1) Kodiak; the largest island, of the same name, is 40 mi. by 100 mi., and may be considered a continuation of the Kenai peninsula. The group's western continuation consists of the Semidi, Shumagin and Sanak clusters; (2) the Aleutian Islands (*q.v.*), sweeping 1,200 mi. or more W.S.W. from the end of Alaska peninsula; west of the mainland in Bering sea, the Pribilof Islands, about 500 mi. S. of Cape Prince of Wales, the small Hall and St. Matthew Islands; to the north, toward Bering strait, the large St. Lawrence Island, with Nunivak near the coast to the southeast. Of the smaller islands within Bering sea, only the Pribilofs (home of the fur seal during breeding season) are of special interest or value.

Alaska has mountains, plateaus and lowlands on a grand scale. "In a broad way, the larger features of topography correspond with those of the western States. There is a Pacific mountain system, a central plateau region, a Rocky mountain system, and a Great plains region. These four divisions are well marked, and show the close geographic relation of this area to the southern part of the continent." But the general features of the Pacific mountain system trend parallel to the coast line of the Gulf of Alaska. The Pacific mountain system includes four ranges. The coast range of the Panhandle attains a width of 100 mi., but has no well-defined crestline. The range is characterized by summit levels between 5,000 and 10,000 ft. Continuing the coast range, with which it is closely associated—the Chilkat river lies between them—is the St. Elias range (a term used to include not only the mountains between Cross sound and Mt. St. Elias but the Chugach, Wrangell and Nutzotin mountains), lying in the southeast of the main peninsula or continental Alaska. Among its principal peaks are: Mt. Sanford, Mt. Fairweather and Mt. Vancouver, all higher than 15,000 ft., and Mt. Wrangell, 14,005 ft. (an active volcano), in the Wrangell mountains, Mt. St. Elias, 18,008 ft., and in Canadian territory, Mt. Logan, 19,850 ft. The Aleutian range, of which crest the Aleutian Islands are remnants, fills out the system near the coast. In the Aleutian range, near the base of the Alaska peninsula, there occurred in the early days of June 1912 one of the great volcanic eruptions of historic times. The top of Katmai, a mountain showing no evidence theretofore of volcanic action, was entirely blown off, and about the same time there came into existence in the valley to the northwest a vast number of tiny volcanic vents or fumaroles, later known as the Valley of Ten Thousand Smokes. The mountain and valley were later set apart by proclamation of the president (Sept. 24, 1918) as the Katmai National monument. The Alaska range, which lies south of the Yukon drainage system, connects with the Nutzotin and Skolai branches of the St. Elias range. It is splendidly marked by many snowy peaks, including Mt. Foraker (17,000 ft.) and Mt. McKinley (20,300 ft.), the loftiest peak in North America. North of the Yukon are the Baird and Endicott mountains of the Brooks range, an extension of the Rocky mountains. Between the Pacific mountains and the last-mentioned ranges lies the vast central plateau region or Yukon plateau. Finally, between the Brooks range and the Arctic ocean is the arctic slope region, a sloping plain corresponding somewhat to the interior plains of the United States.

The glaciers of the Panhandle and throughout the rest of the Pacific region are most remarkable—unusual alike for their number and size. Thousands of alpine glaciers from 1 to 15 mi. long fill the upper valleys and canyons of the mountains. Other glaciers are of the piedmont type. The two most notable glaciers are the Malaspina, largest in the territory, extending 50 mi. along the seaward base of Mt. St. Elias; and the Muir, at the head of the icy straits. The Muir was much visited by tourists prior to the earthquake in 1899, which so shattered the glacier and increased the discharge of ice that steamers no longer found it safe to approach near the face. The condition of the glaciers of Alaska, generally speaking, appears to be one of recession; many of them now have terminal moraines many miles back.

TWO SQUARES SHOWING THE RELATIVE AMOUNT OF SPACE AVAILABLE PER PERSON IN ALASKA (4.5 SQ. MI.) AND IN CONTINENTAL UNITED STATES (12.6 AC.)

Chief among the streams of Alaska is the Yukon, 1,800 mi. in length, which practically bisects the main peninsula. The principal feeders of this great river have their sources far away to the southeast in the coastal mountains along the boundary between Alaska, British Columbia and the Canadian Yukon territory. It flows in a general northwesterly direction for about one-half its length, passing through a small section of British Columbia and through territory of the Canadian Yukon till it reaches the 141st meridian. There it enters U.S. territory and, continuing to the northwestward, passes within the Arctic circle for a short distance in the vicinity of Port Yukon. It then turns southwesterly, gathering volume from many tributaries, the principal of which are the Tanana and the Koyukuk, and finally empties its flood into Bering sea through many mouths and over a vast bar, in longitude (approximately) 164° W. and latitude 63° N. The ocean port for the river, where merchandise is transferred by lighterage from ocean vessels to river boats, is a bay on St. Michael Island, lying about 60 mi. to the northeast of the Northern or Apoon mouth. River boats drawing from three and a half to four feet can enter the Apoon mouth and proceed without difficulty, in ordinary stages of water, practically the whole length of the river to Whitehorse, connecting there with the White pass and Yukon railway to Skagway. The period of navigation on the Yukon is from four to four and a half months. The second largest river in Alaska is the Kuskokwim, with its sources in the mountains of the Alaska range south of the Yukon drainage basin, and emptying into the Bering sea about 150 mi. S. of the mouth of the Yukon. It is navigable for about 600 mi. Out of the Alaska and Nutzotin mountains two great rivers flow southward: the Copper, practically unnavigable except for small boats, because of its turbulence and the discharge of glaciers into its waters; and the Susitna, also practically unnavigable. Both these rivers have their sources in lofty mountain masses, and are swift and powerful streams carrying with them much silt.

The Panhandle is remarkably picturesque. The maze of islands of the Alexander archipelago, hundreds in number, are remnants of a submerged mountain system; the islands rise 3,000 to 5,000 ft. above the sea, with luxuriantly wooded tops and bold, sheer sides scarred with marks of glacial action. Through the inner channels, sheltered from the Pacific by the island rampart, runs the "inland passage," the tourist route northward from Seattle, Wash. The interinsular straits are carried up into the mainland shore as fiords heading in rivers and glaciers. Most remarkable are the inlets known as Tracy Arm and Lynn canal (continuing Chatham strait). The first is very deep, with precipitous shores and bordering mountains 5,000 to 6,000 ft. high; the second is a noble fiord 100 mi. long and on an average 6 mi. wide, with magnificent alpine scenery.

Continental Alaska in the interior is essentially a vast plateau. "The traveller between the main drainage areas of the interior is struck by the uniform elevation. Rounded hills, level meads, and persistent flat-topped ridges, composed of rocks of varying

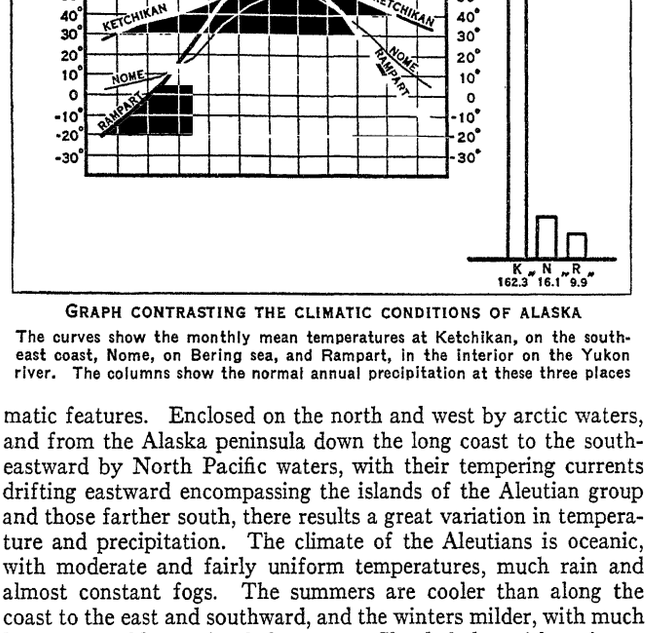
structure, rise to about the same level and give the impression that they are the remnants of a former continuous surface. In height it varies from about 5,000 ft. close to the bases of the mountain systems to less than 3,000 ft. in the vicinity of the main lines of drainage and slopes gradually toward the north."

**Geology.**—The outstanding features of Alaska are its mountain ranges, most of which consist of closely folded and contorted beds of sedimentary rock and underlying igneous masses, by intrusion of which the sedimentary beds were uplifted. A notable mountain chain is the Alaska range, which is nearly 600 mi. long and 50 to 80 mi. wide. This range, which was elevated to its present height late in Tertiary time, marks an old line of movement that has repeatedly been the site of folding and mountain building. In this range is the Mt. McKinley National Park, a reservation that contains 1,939,199.04 ac. and includes the highest peak in North America, Mt. McKinley, which stands 20,300ft. above sea-level. Volcanic products, which were poured out at intervals during an immensely long time, form a part of some ranges and make up most of the mass of many peaks. Among these volcanic peaks are the Wrangell mountains and many of the mountains on Alaska peninsula and in the Aleutian chain of islands. On the other hand, Mt. McKinley and Mt. St. Elias consist of masses of intruded granitic rock surrounded by sedimentary beds. The high relief of the larger mountain masses is due to their relatively recent elevation, the forces of erosion not yet having had time greatly to reduce their height.

The general outline of the mountain ranges in Alaska is a continuation of that seen in the region to the south, in Canada, but the course of the ranges in Alaska swings around from north-west to south-west, toward Asia, and the geologic history of the coastal ranges in both continents is doubtless similar. Far to the north lies Brooks range, from the northern base of which runs a series of gently folded beds that extend to the Arctic ocean.

The details of the geological structure and of the petrology of Alaska are extremely complex, and the attempt to trace the geological history of the region is very difficult. The geological record indicates a long series of periods of uplift and depression, of erosion and deposition, of folding and faulting and metamorphism of the beds deposited, and of intermittent volcanism that produced great areas of lava and ashes, which, like all other deposits, were shifted here and there and at some places greatly altered.

The oldest sedimentary deposits are certain pre-Cambrian rocks that lie in a broad belt in the upper Yukon valley, especially in the region between the Yukon and the Tanana, where they include what is called the Birch Creek schist, the bed rock in that region. The conditions and events in early Cambrian time are unknown, but in late Cambrian and in parts of Ordovician time large areas in Alaska appear to have been submerged, for most of the beds formed during those periods are marine deposits. Evidences of emergence, however, are found at some places. In early Devonian time there was a period of elevation, deformation, and subsidence over large areas. Toward the end of the Carboniferous period, in late Pennsylvanian or early Permian time, marine deposition prevailed, perhaps intermittently, until beds of limestone that measured in the aggregate thousands of feet in thickness were laid down over parts of Alaska. The Palaeozoic beds include at many places accumulations of volcanic material, but the greatest eruptions in Palaeozoic time appear to have occurred intermittently near its end, during the Pennsylvanian and Permian epochs. Most of the products of these eruptions lie south of the Alaska range. In late Permian and early and middle Triassic time Alaska was a land surface undergoing erosion. In late Triassic time depression again brought the sea over a large part of Alaska. This submergence was followed by widely extended uplift, which included probably all of Alaska. In early Jurassic time the Pacific and Arctic coasts were submerged and along them were deposited beds of sandstone, shale and limestone. Middle Jurassic deposits cover a somewhat wider area along the Pacific coast. In Jurassic time there was a persistent shore line near the site of the Alaska range.



In early Cretaceous (lower Cretaceous) time renewed submergence brought the sea over much of Alaska, including parts of the Yukon valley, most of which had been above the sea since the end of Palaeozoic time. A large part of northern Alaska, which had been land since the end of the Triassic period, was also submerged. The deposits of this time include a basal conglomerate and overlying shale and limestone. An uplift and a change in places of sedimentation followed, in later Cretaceous (upper Cretaceous) time, during which the larger topographic features of present Alaska were doubtless outlined. Marine deposits were laid down along the Arctic and Pacific coasts and in the lower and broader parts of the Yukon and probably other valleys. Terrestrial deposits were formed in embayments that stood on the sites of the larger river valleys. The submergence of the Yukon valley gradually increased and as gradually slackened, and swamps were formed in which plants grew and coal beds were laid down. The Cretaceous deposits in the Kuskokwim valley appears to be very similar to those in the lower Yukon valley. While sedimentation was in progress in the Yukon valley the rest of Alaska may have been land. During later Cretaceous time the sea invaded the sites of the Matanuska and Chitina valleys and parts of the southern coastal region. The deposits of this time in Alaska peninsula include marine shale, coal-bearing shale, conglomerate sandstone and shale, probably of mixed marine and terrestrial origin. The end of Cretaceous time on Alaska peninsula appears to have been marked by a period of mountain growth. The Cretaceous beds are greatly folded everywhere and many of them are cut by intrusive rocks and intrusive veins. Deposits of tuff laid down in early Tertiary (Eocene) time show that the diastrophic movements which began late in Cretaceous time culminated in volcanic eruptions. Among the earliest post-Cretaceous deposits are the Tertiary coal-bearing beds. Two groups of coal beds that lie near the Alaska range are reached by the Alaska Railroad, one in the valley of Matanuska river, in lat. 61° 45′, the other along and east of the Nenana river, about lat. 64°. Most of the coal mined is used on the railroad. Beds of lignitic coal are exposed at many places around Cook Inlet and in the lower part of the valley of the Susitna river. The coal-bearing beds, which have been at some places greatly tilted and folded, generally consist of poorly consolidated sand, clay and gravel, and at some places contain abundant remains of plants. Many of the Tertiary rocks, however, consist of hard conglomerate and shale, and include basaltic lava and other volcanic material, as well as intrusive dikes and sills.

By early Quaternary time the great mountain-building movements in the south of the Alaska range had apparently ceased and the larger topographic features of this region, including the Kenai-Chugatch range, the Talkeetna Mountains and the Yukon-Tanana upland, had assumed nearly their present form, although the details of the drainage may have been different, for the climate was milder than it is now. A colder age followed, in which enormous glaciers were formed in the mountains. The Quaternary beds, which include glacial deposits, are widespread. In the Alaska range and in the region south of it such deposits constitute a large part of the unconsolidated surface material. The glaciers abraded the rocks of the highlands and carried down into the lowlands immense quantities of gravel, sand, silt and till, modifying the forms of the higher valleys and leaving thick deposits over large areas. The bluffs along Copper river, for example, consist of glacial deposits more than 500 ft. thick; and moraines, outwash gravel and thick delta fans made up of glacial material cover large areas. The glaciers now appear to be receding, but the deposition of outwash from glaciers is still in active progress at many places, and the great glaciers in the Alaska range and the Wrangell mountains, and especially the glaciers of Kenai Peninsula, Prince William Sound and the coast farther south, are conspicuous features. The higher parts of the Alaska range are the gathering grounds for some of the largest valley glaciers Five or more of these great tongues of ice are from 2 to 4 mi. wide and 30 to 50 mi. long. The present surface form of the mountains of this range has been produced in large part by the erosive action of these glaciers and of their much larger predecessors.

Great changes in the climate of north-western North America are indicated by the fossil plants. The flora of Alaska was at times evidently that of a temperate or a warmer region.

The uplifts in Alaska apparently established land connection between North America and Asia at several periods. Across this body of land in Tertiary time horses of early types passed to Asia from the central plains of North America, which appear to have been the first habitat of the horse. Early elephants, or elephant-like creatures, on the other hand, found their way from Asia to America, where their remains have been discovered at many places.

**Climate.**—Alaska is one of the "ends of the earth" and as such presents many interesting extremes, none more than in its climatic features. Enclosed on the north and west by arctic waters, and from the Alaska peninsula down the long coast to the southeastward by North Pacific waters, with their tempering currents drifting eastward encompassing the islands of the Aleutian group and those farther south, there results a great variation in temperature and precipitation. The climate of the Aleutians is oceanic, with moderate and fairly uniform temperatures, much rain and almost constant fogs. The summers are cooler than along the coast to the east and southward, and the winters milder, with much less snow, seldom going below zero. Clouds laden with moisture from the warm Pacific currents, being swept in upon the mountains and the many glaciers by the prevailing winds, produce a heavy precipitation of rain in summer and snow in winter. Across the coast range in the interior there is an entirely different climate. There the precipitation, of both rain and snow, is comparatively light except upon the high mountain ranges. Low temperatures occur in winter—occasionally as low as −75° or −80° F.—with short, hot summers. In this part of Alaska the ground is permanently frozen to great depth in most of the valleys, but on the drier hillside slopes it frequently happens that but little frost is found. The tempering influence of the ocean currents practically disappears north of the line of the Pribilof Islands, or about the middle of Bering sea, and the regions to the northward and eastward of this are for the most part barren, windswept and inhospitable. Arctic conditions prevail, especially beyond Bering strait. Point Barrow, farthest north (71° plus), is ice-locked for about ten months of the year.

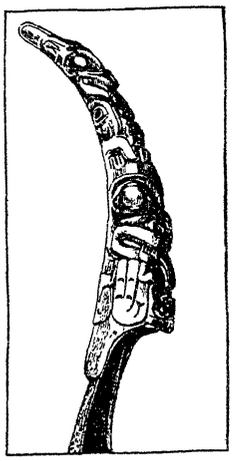
GRAPH CONTRASTING THE CLIMATIC CONDITIONS OF ALASKA

The curves show the monthly mean temperatures at Ketchikan, on the southeast coast, Nome, on Bering sea, and Rampart, in the interior on the Yukon river. The columns show the normal annual precipitation at these three places

**Fauna and Flora.**—The fauna of Alaska is very rich and surprisingly varied. The lists of insects, birds and mammals are especially noteworthy. Of these three classes, and of other than purely zoological interest, are mosquitoes, which swarm in summer in the interior in vast numbers; seafowl, which are remarkably abundant near the Aleutians; moose, and especially caribou, which in the past were very numerous in the interior and were of economic importance to the natives. The destruction of the wild-life threatened to expose the Eskimos to starvation, hence the effort made by the United States government to stock western Alaska with domestic reindeer from Siberia. It is, however, the fish and fur-bearing animals of its rivers and surrounding seas that are economically most distinctive of and important to Alaska. The fishing grounds extend along the coast from the extreme southeast past the Aleutians into Bristol bay.

Herring, cod and salmon abound in almost incredible numbers. Of marine mammals, whales are hunted far to the north in Bering sea and the Arctic ocean, but are much less common than formerly as are also the walrus, the sea otter and the sea lion. Fur seals are increasing in number because of effective government control. The number of fur-bearing land animals is equally large. Sable, ermine, wolverine, mink, land otter, beaver and muskrat have always been important items in the fur trade. There are black, grizzly and polar bears and also two exclusively Alaskan species, the Kodiak (or Kadiak) and the glacier bear. The gray wolf is common; it is the basal stock of the Alaskan sledge dog. The red fox is widely distributed, and the white or arctic fox is very common along the eastern coast of Bering sea. A blue fox, once wild, is now domesticated on Kodiak, the Aleutians and the southern continental coast, and a black fox, very rare, is found in southeastern Alaska. The silver fox is very rare.

The Alaskan flora is no less varied than the fauna. Wildflowers are alpine in size, colour and profusion. The forests of the coastal region, though hitherto almost unutilized, are of potential value. The balsam fir and in the south the red cedar are found in scant numbers; more widely distributed, but growing only under marked local conditions, is the yellow or Alaska cedar, a very hard and durable wood of fine grain and pleasant odour. Far the most abundant are coast and alpine hemlocks and the tideland or Sitka spruce. The spruce is not confined to this part of Alaska, but is the characteristic and universal tree. The separation of the coast and interior flora is almost complete; only along the mountain passes and river valleys, and rarely there, is there any change of species. Timber, however, is fairly abundant along the entire course of the Yukon above Anvik (about 400 mi. from the mouth), along the great tributaries of the Yukon and along every stream in central Alaska. The woods of the interior consist almost entirely of spruce. On the Yukon flats it grows in a vast forest impenetrably dense. The timber line, which in the Panhandle and along the southern coast of the continental mass runs from 1,800 to 2,400 ft., frequently rises in the interior plateau even to 4,000 ft. Next in importance after spruce in the interior is birch and then balsam poplar. Thickets of alders and willows in wet places and new-made land, aspens and large cottonwoods west of the characteristic spruce area (as on Seward peninsula) are also common. Toward the Arctic circle the timber becomes, of course, sparse, low, gnarled and distorted. The willows in the arctic drainage basin shrink to shrubs scarcely knee-high. Grasses grow luxuriantly in the river bottom and wherever the tundra moss is destroyed to give them footing. Most distinctive is the ubiquitous carpeting of mosses, varying in colours from the pure white and cream of the reindeer moss to the deep green and brown of the peat moss, all conspicuously spangled in the brief summer with bright flowers of the higher orders, heavy blossoms on stunted stalks.



Sedges available for forage grow in the tundra. In August berries are fairly abundant over the interior; one of them, the salmonberry or cloudberry, preserved in seal oil for the winter, is an important food of the natives. The western timber limit is on Kodiak Island. The Aleutian Islands are almost destitute of trees, but are covered with a luxuriant growth of herbage. Climatic differences cannot account for the treeless condition of the country west of this point, and the true explanation lies probably in the fact that in winter, when the seeds of the coastal forests ripen and are released, the prevalent winds west of Kodiak are damp and blow from the south and southwest, while the spread of the seeds requires dry winds blowing from the north and northwest. Such favourable conditions occur only rarely.

**Exploration and Early History.**—In the early explorations of the northwest coast of America, Spain was first in the field but there is little evidence to prove that any Spanish navigator sailed as far north as Alaska. Later, and during the period of active Russian exploration, a number of expeditions were sent north from Mexico and at one time Spain claimed the sole right

to navigate the waters of the northern Pacific and issued a prohibition against other nations trading in those waters. Many Spanish names of places along the coast remain today to attest the extent of these explorations. Spain does not appear to have pressed her claims, however, and gradually ceased her efforts in this direction. This may have been because of disputes on her hands in other parts of the world or the wide extent at that time of the Spanish claims in the western hemisphere or possibly, in part, the fact that the climatic conditions of this northern region did not appeal strongly to a people whose life and activities had been spent in warmer climes. To the Russian, on the other hand, these regions were as home.

During the latter half of the 17th century the Russians had been pushing their explorations across Siberia and along the eastern and northern shores of Asia. In 1728 Vitus Bering passed through the strait named after him and Girosdeff sighted the American coast in 1731. Bering's second expedition, in company with Alexei Chirikov, sailed from the Siberian coast in 1741. The mainland of America was located and numerous islands visited. This expedition is commonly accepted as fixing the date of the discovery of Alaska. Bering's ship was wrecked in early November on what is now called Bering Island. The crew made such provision as was possible against the cold of the approaching winter, but the privations and hardships were very great. "It was under such circumstances that Vitus Bering died—on this cold, forbidding isle, under the sky of an Arctic winter, December 8, 1741." During the 30 or 35 years following, the Russians were active in exploring the coast and islands and in establishing a trade with the natives.

About the time the American colonies were making their struggle for separation from the mother country, England was beginning her part of the exploration of this northwest coast. Three names stand high in the record of these explorations: James Cook, George Vancouver and Sir Alexander Mackenzie. Cook's expedition sailed from England in July 1776. In the personnel of his expedition were men from the American colonies, and Vancouver, then a midshipman, was of the party. The work begun by Cook was continued by Vancouver during the years 1791 to 1794. W. H. Dall expressed the view generally held concerning Vancouver's work in the statement that: "The explorations which he carried out have not been excelled by any other navigator and were faithfully and thoroughly performed." The Hudson's Bay company was meanwhile advancing its trade and extending its influence westward from the interior of Canada. In 1793 Mackenzie crossed the continent by land to the Gulf of Georgia, returning by the same route. This expedition, although little known, may well be compared with that of Meriwether Lewis and William Clark, in respect both of the difficulties encountered and of its value to his company and government.

CARVED WOODEN SPOON USED BY THE INDIANS OF ALASKA

The excesses committed by private traders and companies, who robbed, massacred and hideously abused the native Indians, caused the Russian government in 1799 to confine the trade and regulation of its American possessions to a semiofficial corporation called the Russian-American company for a term of 20 years, afterward twice renewed for similar periods. Alexander Baranof, chief resident director of the American companies (1790–1819), and one of the administrators of the new company, became famous through the success he achieved as governor. He founded Sitka (*q.v.*) in 1804 after the massacre by the natives of the inhabitants of an earlier settlement (1799) at an adjacent point. The headquarters of the company were at Kodiak until 1805, and thereafter at Sitka.

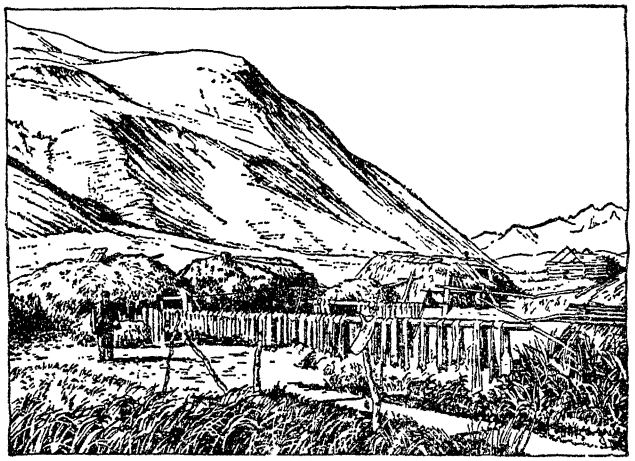
In 1821 Russia attempted by ukase to exclude navigators from Bering sea and the Pacific coast of her possessions. This led to immediate protest from the United States and Great Britain. The outcome was a treaty with the United States in 1824 and one with Great Britain in 1825, by which the excessive demands of Russia were relinquished and the boundaries of the Russian possessions were established. In the convention with Great Britain, it was agreed that Russia should have the narrow strip of coast north of 54° 40′ and the peninsula and islands westward of the 141st meridian.

The last charter of the Russian-American company expired on Dec. 31, 1861, and Prince Maksutov, an imperial governor, was appointed to administer the affairs of the territory. Authority was granted to an American company in 1864 to make explorations for a proposed Russo-American company's telegraph line overland from the Amur river in Siberia to Bering strait, and through Alaska to British Columbia.

Work was begun on this scheme in 1865 and continued for nearly three years, when the success of the Atlantic cable rendered the construction of the line unnecessary and it was given up, but not until important explorations had been made. Much of this information was made public in 1870 by W. H. Dall in his book *Alaska and its Resources.*

The first official overtures by the United States for the purchase of Russian America were made by Sen. William Gwin of California (1859) during the presidency of James Buchanan. This movement, however, was checked temporarily by the Civil War, which soon followed.

The fishing interests of northwestern United States were next to manifest an interest in the territory to the northward. In 1866 a memorial was adopted by the legislature of the Washington territory, "in reference to the cod and other fisheries," and delivered to Pres. Andrew Johnson. By a treaty signed on March 30, 1867, the purchase was consummated for the sum of $7,200,000, and on Oct. 18, 1867, the formal transfer of the territory was made at Sitka.



**Later History.**—After its acquisition by the United States, the history of Alaska was mainly that of the evolution of its administrative system and the varying fortunes of its gold fields, fisheries and sealing industries. Alaska was an unorganized territory from 1867 until May 1884. From 1867–77 the government was in the hands of the department of war, although the customs were from the beginning collected by the treasury, with which the control rested from 1877 until the passage of the so-called Organic act of May 17, 1884. This act extended over Alaska the laws of the state of Oregon so far as they should be applicable, created a judicial district and a land district, put in force the mining laws of the United States and in general gave the administrative system the organization it retained up to the reforms of 1899 and 1900. The history of government and political agitation then centred in the demand for general land legislation and for an adequate civil and criminal law, in protest against the enforcement of a liquor prohibition act, and in agitation for an efficiently centralized administration. After partial and inadequate legislation from 1891 to 1898, the regular system of land surveys was made applicable to Alaska in 1899, and a generous homestead law was provided in 1903. The liberal land policy was completely reversed as a result of the conservation movement inaugurated under Pres. Theodore Roosevelt. The original aim of the movement was to prevent waste of natural resources, but this gradually veered to a protest against corporate control of lands and resources.

An important result of the conservation movement was the increase of reservations in Alaska, about 40,000 sq.mi. being set aside for various purposes, exclusive of mineral and forest withdrawals. For many years, however, the conservation issue remained unsettled and industry languished; with an abundant supply of fuel close at hand, Alaska was forced to import petroleum and coal at great cost; her pulp wood was rotting in the forests; her water power was undeveloped. Only gold and copper mining and salmon fishing increased. Finally during the Woodrow Wilson administration, a leasing policy for coal and oil lands and water power was established by law.

The struggle of Alaska to attain representation at Washington,

D.C., resulted in 1906 in the authorization of an elected delegate to congress. At each biennial election which followed, home rule was the only important issue, until in 1912 an act was passed granting a limited territorial government. The first territorial legislature was convened at Juneau on March 3, 1913, and the first law passed gave the franchise to women.

The agitation over prohibition dated from 1868; the act of that year organizing a customs district forbade the importation and sale of firearms, ammunition and distilled spirits; the Organic act of 1884 extended this prohibition to all intoxicating liquors. Smuggling flourished; juries steadily refused to convict offenders and treasury officials regularly collected revenue from saloons existing in defiance of law. In 1900 the sale of liquors was authorized under a high licence law. In 1917 congress responded to a legislative petition by passing a dry law for Alaska. In 1940 the people of Alaska rejected territorial liquor control by referendum.

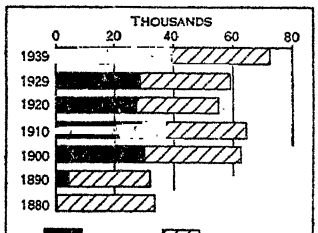
**NATIVE METHOD OF DRYING SALMON EMPLOYED IN WESTERN ALASKA**
In summer the Alaskan Indian catches a great quantity of salmon, which is hung over poles to dry and then stored for the winter months

Two events of international interest growing out of Alaska were the fur seal arbitration of 1893 (*see* BERING SEA ARBITRATION), and the Alaskan-Canadian boundary dispute, previously mentioned, settled by an international tribunal of British and American jurists in London in 1903. The boundary dispute involved the interpretation of the words in the treaties of 1825 and 1867 defining the boundary of the Russian (later U.S.) possessions, and also the determining ownership of the Portland canal and the question whether the coastal girdle should cross or pass around the heads of the fjords of the coast. The award of the tribunal made in Oct. 1903 was arrived at by the favourable vote of the three commissioners of the United States and of Lord Alverstone, whose action was bitterly resented by the two Canadian commissioners; it sustained in the main the claims of the United States.

Very little was known about the interior of Alaska previous to 1896, when the gold discoveries in the Klondike stimulated public interest regarding it. From 1895, however, explorations of the United States geological survey and the department of war, as well as those of individuals, established the main features of its physiography and a rather accurate knowledge of its resources.



The federal government began to expand its military establishment in the territory in 1939, after belatedly recognizing the strategic importance of Alaska as a northerly and westerly outpost in the nation's defense system. Throughout World War II Alaska was a vitally important link in the new air routes to the U.S.S.R. During the conflict, this northwestern province, extending from a point 700 mi. N. of Seattle to within sight of the mainland of far eastern Russia, entered increasingly into U.S. national consciousness as the struggle progressed—first, as the objective of Japanese aggression, next, as an important take-off point for attacking Japan, and finally, with peace, as a new frontier for war veterans. Many new airports were constructed throughout Alaska and the first land link between the territory and the continental United States was completed with construction of the Alaska highway. Vast military expenditures, plus scores of new service industries resulted in substantial increase in the economic levels of almost all regions of the territory; there was no mass exodus of population from Alaska at the war's end.

Accompanying the economic progress was considerable political progress. Alaskans in 1946 voiced their demand for statehood at the ballot box. The appeal for statehood was by no means a new desire, as numerous bills had been introduced in the congress of the United States calling for statehood for Alaska during the preceding years. Backed by the results of the 1946 referendum, Alaska's delegate to congress introduced another bill for Alaska statehood and for the first time congressional hearings were held on the subject. During 1947 and 1948, hearings were held both in Alaska and Washington, D.C. On April 14, 1948, the house committee on public lands reported favourably on a bill to provide for admission of Alaska to the union. The measure, however, did not reach the floor of the house. During the first session of the 81st congress, 1949, the measure again received approval of the committee, and again failed to reach the house for action. It was not until the second session that the house of representatives passed the statehood measure. The senate, however, did not act on the bill during its regular session.

**Population.**—The population in 1867, at the time of the cession from Russia, was estimated at 30,000, made up mainly of Eskimos and other natives. The population in 1880, at the time of the first enumeration by the United States, was 33,426, which number included only a few hundred white persons: in 1900 it was 63,592 and in 1910, 64,356, while in 1920, partly by reason of the decline in the gold-mining industry, the census recorded only 55,036. In the next census (1929), the population was 59,278; in the 1939 census, 72,524—the latter figure representing an increase of 22.3% over 1929. Of this number, 30,384 were native whites, 8,786 were foreign-born whites and 33,354 were nonwhites, mainly persons of native stock. Of the 8,786 foreign-born whites, 2,444 were born in Norway, 1,223 in Sweden, 1,051 in Canada, 665 in Finland and 589 in Germany. No other country contributed as many as 400. Of the 33,354 nonwhite persons, 32,458 were of native stock, comprising 15,576 Eskimos, 5,599 Aleuts and 11,283 Indians.

According to the 1950 census, taken as of April 1, there were 128,643 persons in Alaska, representing an increase of 77.4% over the previous census count, and the largest increase, percentage-wise, of any state or territory. A substantially larger increase would have been recorded but for the almost absolute lack of housing facilities to accommodate those who were desirous of settling in Alaska, many of whom gave up their plans on finding it impossible to secure residential accommodations, and returned to the states

In the native white population there were 18,651 males and only 11,733 females, making a sex ratio of 159.0 males per 100 females. The foreign-born white population was even more dominantly male, there being 377 males per 100 females. In the native white population, 5.9% were 65 years old or over; in the foreign-born white, 9.3%; and in the native stock, 2.9%. There were 28,936 employed persons 14 years old or over in the labour force in 1939, of whom 5,061 were engaged in agriculture and trapping (mainly in hunting and trapping), 3,207 in fishing, 4,997 in mining, 4,630 in manufacturing and construction, 4,290 in transportation and trade, and 1,677 in professional and related services. In June, July and August of 1939, however, more than 10,000 persons, largely seasonal workers from the states, were employed in the canning industry.

COURTESY OF U.S. CENSUS BUREAU

**POPULATION: 1880-1939**

The towns of Alaska are all small but they are centres for busi-

ness and social activities, as well as for government agencies, each serving a wide tributary area, and are therefore relatively more important than towns of similar size in more populous regions. The population of the territory and its principal cities and incorporated towns is summarized in the accompanying table.

| Area | Population | | | Per cent of increase | |
|---|---|---|---|---|---|
| | 1950 (April 1) | 1939 (Oct. 1) | 1929 (Oct. 1) | 1939–50 | 1929–39 |
| The territory | 128,643 | 72,524 | 59,278 | 77.4 | 22.3 |
| Urban* | 27,705 | 17,374 | 7,749 | 59.5 | 24.2 |
| Rural | 100,938 | 55,150 | 51,529 | 83.0 | 7.0 |
| Per cent urban | 21.5 | 24.0 | 13.1 | — | — |
| Principal cities:† | | | | | |
| Anchorage | 11,060 | 3,495 | 2,277 | 216.5 | 53.5 |
| Juneau | 5,818 | 5,729 | 4,043 | 1.6 | 41.7 |
| Fairbanks | 5,625 | 3,455 | 2,101 | 62.8 | 64.4 |
| Ketchikan | 5,202 | 4,695 | 3,796 | 10.8 | 23.7 |
| Sitka | 2,080 | 1,987 | 1,056 | 4.7 | 88.2 |
| Seward | 2,063 | 949 | 835 | 117.4 | 13.5 |
| Nome | 1,852 | 1,559 | 1,213 | 18.8 | 28.5 |
| Kodiak | 1,635 | 864 | 442 | 89.2 | 95.4 |
| Petersburg | 1,605 | 1,323 | 1,252 | 21.3 | 5.7 |
| Wrangell | 1,227 | 1,162 | 948 | 5.6 | 22.6 |

*Population of cities and towns having 2,500 inhabitants or more; 1950 data preliminary.
†Figures for 1950 based on a preliminary, but approximately complete, count of the census returns.

**Government.**—Alaska's first legislature, which met in 1913 and was patterned after the Washington Territorial act of 1853, consisted of 8 senators and 16 representatives elected from the territory's four judicial divisions. In 1950 the Alaska territorial legislature consisted of 4 senators from each of the four judicial divisions elected to four-year terms and 24 representatives, apportioned in proportion to population, elected to two-year terms, the representation being eight, seven, five and four from the first, third, fourth and second divisions respectively. The members' salaries and transportation to and from the legislative sessions are paid by the federal government. The legislature convenes biennially in odd years for a period not to exceed 60 days, to legislate on territorial matters, not specifically prohibited by the Organic act, adopt a biennial budget and pass on the governor's appointments. The governor is empowered when the need arises to call a special session which may not continue longer than 30 days.

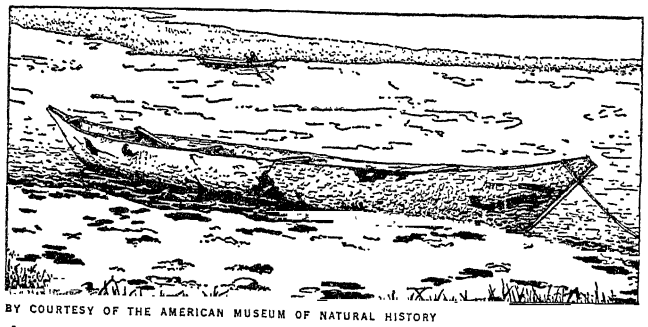
The actual government of Alaska is both federal and territorial. Both the governor and secretary of Alaska are appointed for four-year terms by the president of the United States, the former subject to confirmation by the United States senate. In the governor's absence from the territory, the secretary is acting governor. In some instances the federal and territorial functions overlap; in others they are separate and distinct.

There are four judicial divisions in Alaska with headquarters at Juneau, Nome, Anchorage and Fairbanks. A federal district judge, United States attorney and United States marshal—all presidentially appointed—preside over each. In addition to their judicial duties, the judges issue liquor licences and dispense a small fund for indigents. They likewise appoint the United States commissioners, of whom there were 53 in 1949. The commissioners act as local court magistrates, probate judges and coroners, are unsalaried but paid through a variety of fees. There are no territorial courts. The commissioner's courts have jurisdiction in probate, insanity and minor civil and criminal matters arising under the federal statutes applicable to the territory under territorial laws. Additionally, each incorporated municipality has a magistrate court which has jurisdiction over matters arising under local ordinances. The district courts have the same general original jurisdiction as similar courts in the continental United States, having in addition general jurisdiction in civil, criminal, equity and admiralty cases. Prior to 1947 the marshal's office had the sole responsibility for the maintenance of law and order outside of incorporated towns. In 1947 members of the Alaska highway patrol, a territorial police force, were given full police powers and the authority of the United States marshal. They also were appointed deputy game wardens.

Among the various federal departments operating in Alaska are the department of interior, department of agriculture, department of commerce, department of labour and the treasury department. Other executive departments of the federal government exercise the same administration respectively in Alaska that they do in other parts of the United States, and virtually every executive branch of the government was represented by mid-20th century.

The principal territorial officers are the attorney general, treasurer, auditor, highway engineer and commissioner of labour, all nominated in party primaries and elected by popular vote for four-year terms. These officials, together with a commissioner of education and the governor, constitute the board of administration which exercises limited administrative functions between legislative sessions. Other territorial officials, such as the commissioners of agriculture, mines and taxation, are appointed by the governor and subject to confirmation by the legislature. Alaska elects its delegate to the federal congress for a two-year term. He represents the territory, is a member of a number of committees in the house of representatives and can speak on the floor as well as introduce bills, but has no vote. The political parties of Alaska send delegates to national conventions where candidates for president and vice-president of the United States are nominated, but Alaska has no vote in the electoral college. All citizens of Alaska—whites, Indians, Aleuts and Eskimos—have the right to vote and in the 1950 election two Eskimos were elected to the senate and two Indians and one Eskimo to the house. The principal territorial agencies are the department of education, department of health, department of public welfare, department of mines, department of agriculture, Alaska veterans affairs commission, department of fisheries, department of aviation and Alaska development board. The latter agency, created by the territorial legislature in 1945, directs most of its activities in behalf of new and expanded industrial and business enterprises in Alaska.

**Finances.**—The budget for the 1951–53 biennium, exclusive of expenditures for roads, waterfront improvements and airfields, which are financed out of fuel tax receipts, was $17,973,645, the major items of which were $8,077,688 for education, $2,896,000 for welfare, and $999,000 for health. The governor can veto bills and any specific item in the appropriation bill, but may be overridden by a two-thirds vote of the two houses polling separately.



The fiscal system of the territory underwent a pronounced change at the 1949 session of the territorial legislature. The old licence statute enacted by congress in 1899 and 1900, under which the federal government collected licence fees on certain occupations, professions and lines of business and through the Alaska fund turned them over to the territory, was repealed by an act of congress. The legislature enacted a number of revenue statutes including an income tax on persons and corporations, a business licence tax on occupations, professions and various lines of business, a definite percentage tax on the sale of canned salmon, a raw fish tax, a resident and nonresident fisherman's licence tax, a tax on tobacco and tobacco products, a motor-fuel tax, a graduated tax on fish traps, a tax on automobiles and on drivers and a general property tax. These, together with the old tax on liquor and school tax, constituted the principal source of territorial revenue. For the fiscal year ending June 30, 1950, the department of taxation collected a gross total of $9,232,421.06.

There were 17 territorial and 4 national banks operating in Alaska on June 30, 1950, with a combined capital of $1,505,000, surplus and undivided profits of $3,572,914.62 and total deposits of $78,103,948.91.

**Education and Welfare.**—By an amendment to the Organic act passed in 1917, Alaska became responsible for the education of its white population. The Alaska division of the office of Indian affairs, department of the interior, is required to provide for the education of the natives, to train them in industry and to furnish them medical relief. The enrolment in the territorial schools for the session 1949–50 was 13,908 pupils and 544 teachers. Of the total enrolment, 2,418 were in high schools and 11,490 in elementary schools. The school term in incorporated towns ranged from nine to ten months and for rural districts from seven to nine months. During the fiscal year 1950 there were 4,082 natives in the 83 schools supported by the federal government. There were in addition 902 students attending 16 parochial schools. The only

institution of higher education is the land-grant University of Alaska opened at Fairbanks in 1922. Its enrolment for 1949–50 was 509 and 972 were registered in short courses.

The burden of welfare falls on both the territorial and federal governments. The insane of Alaska are cared for at federal expense in a private institution.

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

A DUGOUT CANOE OF THE TLINGIT INDIAN, A MEMBER OF ONE OF THE FOUR ETHNOLOGICAL RACES IN ALASKA. THE TLINGIT ARE SKILLED FISHERMEN AND HUNTERS, WHO FASHION THEIR CANOES FROM CEDAR LOGS. THE CRAFT VARY IN SIZE AND SHAPE ACCORDING TO PURPOSE. THE TYPE ABOVE IS USED ON INTERIOR WATERS

**Fisheries.**—The product of the fisheries is about equal to the sum total of all other Alaskan products. The total value of fish marketed between 1867 and 1949 was $1,930,112,109. In 1949 Alaskan fisheries employed about 33,000 people. The total value of Alaskan fishery products in 1949 was $98,904,063, a decrease of $58,799,570 from 1939.

The pack of canned salmon in 1949 was 4,391,051 cases. Halibut products in 1949 were valued at $4,800,000, an increase of more than $4,300,000 over 1939. Operators of this particular fishing industry are governed by a voluntary production-control program and by regulations of the International Fisheries commission. Despite the existence of cod-fishing banks from 22 to 90 fm. deep in the Bering sea and east of the Alaska peninsula, little has been done to exploit the enormous cod resources. Whale fishing was suspended during World War II and had not yet been resumed in 1950 because of various economic factors.

Crab, clams and shrimp assumed an important position in Alaska's canning and packing industry. Utilization of fish waste in the production of fish meal, oils and fertilizer also is important. The total value of these products in 1949 was $2,364,966.

**Agriculture and Livestock.**—In 1950 the best-developed farming areas were in the Matanuska and Tanana valleys where vegetables and poultry were being raised in unprecedented quantities. There is an abundance of good grazing land in the interior, but the period of winter feeding is about eight months.

The Matanuska valley had proved particularly adapted for breeding dairy cattle. The domesticated reindeer herds in 1949 were estimated at 30,000 head, a reduction of 220,000 during the past ten years. It is estimated that Alaska contains 256,000,000 ac. suitable for grazing of reindeer and capable of supporting 10,000,000 deer.

This industry, however, promises little for the future of Alaska except insofar as it may contribute to the sustenance of the Eskimos.

**Furs.**—Between 1867 and 1949 Alaska produced furs to the value of about $192,500,000, of which about 55% represented sealskins taken on the Pribilof Islands. Value of furs shipped from Alaska to the United States during 1949 was $2,075,547, exclusive of sealskins from the Pribilof Islands. Up to 1910 the government leased the seal-catching privileges on these islands to private corporations, which killed 2,320,028 seals and paid the government $9,474,000 in royalties. The land killing of seal was restricted, but pelagic sealing, which was becoming very destructive, could not be controlled by the U.S. government; a treaty was therefore signed in 1911 between the United States, Great Britain, Russia and Japan, abolishing pelagic sealing and providing that the United States was to pay to both Great Britain and Japan 15% of the value of the catch made on the islands. From 1910 killing was prohibited on the Pribilof Islands, except by U.S. agents.

Thanks to these provisions the seal herd increased from 215,000 in 1912 to 3,837,131 in 1949. In 1949, 70,142 sealskins were taken from the herd.

**Minerals.**—As early as 1861 gold discoveries were made on the Stikine river; repeated discoveries, culminating in the Cassiar district "boom," were made in British Columbia from 1857 to 1874; colourings along the Yukon were reported in 1866–67 and systematic prospecting of the upper river began about 1873. Juneau was founded in 1880; the same year the opposition of the Indians, which prevented the crossing of the mountain passes to the interior, was withdrawn, and after 1880 repeated and scattered discoveries were made on the Lewes, Pelly, Stewart and other streams of the upper Yukon country in Canada. As early as 1883–85 there was a considerable mining excitement caused by these discoveries, and a much greater one in 1887 after the discovery of coarse gold on Forty Mile creek in U.S. territory; but these were as nothing to the picturesque and feverish rush that followed the location of the first Klondike claim in Canadian territory in Aug. 1896.

The total value of the mineral output of the territory from 1880 through 1949 was approximately $975,000,000. Of this $535,936,000 was for gold, $227,408,400 for copper and $13,622,000 for silver. Alaska also produces coal, lead, tin, platinum, palladium, antimony, tungsten, natural gas, petroleum, marble, gypsum, graphite, barite and sulphur. Copper mining, begun in 1901, was the chief mineral industry for many years, but in 1930 production of that ore began to fall rapidly at the same time gold production expanded. Thus, while the value of the two was close in 1928, the gold output of 1949 was $8,029,560, as compared with a copper production of but $1,576. Coal, both bituminous and anthracite, occurs in the Bering river and the Matanuska fields, which lie within reach of the government railway. The territory also contains an abundant supply of subbituminous and lignite coals, which are widely distributed. The production up to and including 1949 had a value of $31,626,567 with the output for that year standing at 430,000 tons worth $2,205,900.

Important oil seepages were found at five places on the Pacific seaboard, and at two places in the naval petroleum reserve no. 4 on the north Arctic coast. The withdrawal of all oil lands from entry in 1911 stopped development until 1919, when an oil-leasing law was passed and operations begun in several localities. The production of petroleum, however, was confined to the Katalla field; and when a fire destroyed that refinery in 1933 production was entirely discontinued. The U.S. navy at mid-century was exploring the Arctic field. About 16,500,000 oz. of silver and 18,000 tons of lead had been produced. Almost all the tin output of North America comes from Alaska, chiefly from the York district in the Seward peninsula. The mining of platinum and related minerals began in 1916. Although platinum mining operations expanded during and after World War II, production figures were not announced. Quicksilver mining is carried on in a small way, and in southeastern Alaska high-grade marble is quarried.

**Timber Production.**—The commercial timber of Alaska is contained in the two great national forests, the Tongass in southeastern Alaska and the Chugach on Prince William sound. They had, in 1940, a total area of 20,878,000 ac., and are estimated to contain 84,000,000,000 bd.ft. of saw timber, of which 73% is western hemlock and 20% Sitka spruce. The remainder is largely western red cedar and Alaskan cedar.

Volume of timber cut in 1949 was 56,000,000 bd.ft.; the stumpage value was $114,056.

**Communication and Transportation.**—All commercial communication channels between the territory and the continental United States are operated and maintained by the Alaska Communications system, a branch of the United States army signal corps. Telephone and telegraph services are handled over landlines, cable lines and radio channels. Established in 1900, the Alaska Communications system at mid-century was operating 14 main and 18 substations in Alaska serving military, federal and territorial government agencies and the general public. Total cash receipts for the fiscal year ending June 30, 1950, amounted to

$1,102,213.15. An extensive system of radiotelephone stations in isolated communities was established by the Alaska Communications commission, an agency of the territorial government. The Alaska native service operated a total of 102 radiotelephone stations in 1950, the majority located in the arctic regions. There were 14 community telephone exchanges in Alaska with a total of 11,763 instruments.

There were six daily, nine weekly, one bi-weekly and two tri-weekly newspapers published in the territory in 1950, and ten radio broadcasting stations were in operation.

Lack of adequate land transportation routes between Alaska and the United States had a profound effect on the territory's development. The ruts of the oxcart and the covered wagon, the rails and ties flung across the American frontier, were forerunners of development in the western states, but it was many years after much of the early pioneering had been accomplished that transportation routes—highways and railways—were developed in Alaska. Two United States and three Canadian steamship companies regularly serve Alaska as common carriers. In addition several concerns operate as contract carriers in the freight field and on special cruise runs handling passengers. In addition to the common carriers, there were in 1950 about 12,000 vessels of various descriptions used in the fishing industry and for recreational and personal transportation.

Aviation was a pioneer industry in Alaska. Because of the vast distances and rugged terrain separating communities, the aeroplane quickly became the accepted mode of transportation. The first air-mail service began in 1924. By 1950 seven air carriers were certified for operation over 10,064 route miles. In addition, two domestic and one foreign air carrier operated scheduled service over 6,177 route miles within the territory.

Prior to World War II Alaska had no highway system. The principal highway at that time was the Richardson, linking Valdez with Fairbanks. War construction joined the Anchorage road system with the 371-mi. Richardson highway by means of the 194-mi. Glenn highway, connected the Nabesna road with the Alaska International highway, and extended the 42 mi. of the Haines boundary road to connect with the Alaska highway in the Yukon Territory In 1950 Alaska had an interior highway system of 2,871 mi. There were in addition 356 mi. of road in the national forests, the majority leading from southeastern Alaska communities.

Constructed at the turn of the 20th century, the 111-mi. White Pass and Yukon route extending from tidewater at Skagway to Whitehorse in the Yukon Territory was the first railway built in Alaska. Only 20 mi. of this railway, however, lie in the territory. The United States government authorized construction of the Alaska railroad in 1914. The rail lines were completed from the port of Seward to Fairbanks, a distance of 470 mi., in 1923 at a cost of $56,000,000. During the fiscal year ending June 30, 1950, the railroad transported 875,561 revenue tons and 104,300 passengers. Its assets were valued at approximately $83,500,000.

(E. GRU.)

**ALASTOR,** in early Greek mythology, the spirit of revenge, that prompts the members of a family to commit fresh crimes to obtain satisfaction. Further acts of vengeance transmit the curse from generation to generation. The word is also used for a man's evil genius which drives him to sin; a man so driven is sometimes called *Alastor.* The epithet is applied to the Furies (Erinyes) as the deities of revenge, and to Zeus when he is invoked as the "Avenger."

**ALA-TAU** (variegated mountains) is the name given to the following ranges in Asiatic Russia: (1) Terskei, (2) Kunghei and (3) Trans-ili, all three linking the Tian Shan and the Alexander range. (1) Lies south, and (2) and (3) north of and parallel to Lake Issyk-Kul. Average height 6,000–7,000 ft. (Mt. Talgar 14,990 ft.). Snow-line 11,000–11,700 ft. (4) Also called Talastau, west by south from the Alexander range. (5) Dzungarian Alatau, a range bordering the Dzungarian gate, north of the Tianshan, average height 6,250 ft., max. 11,000 ft. (6) Kuznetsk-Alatau, between the upper Ob and the upper Yenisei, west of the Abakan mountains.

Average height 6,000–7,000 ft.

**ALATYR,** a town in Chuvash, A.S.S.R. Pop. (1935) 22,689. It is situated in latitude 54° 53′ N. and longitude 46° 30′ E., at the junction of the Alatyr and Sura rivers. It has a grain elevator and an extensive grain trade, also flour mills and starch factories.

**ALAUNA, ALAUNUS,** the Celtic names of two rivers, etc., in Roman Britain. Hence the modern Allan Water, river Alyn, etc.

**ALAUSÍ,** a town in the inter-Andine province of Chimborazo, Ecuador, on the Guayaquil-Quito railway and the proposed route of the Pan-American highway. The town is in the plain of Alausí and on the river of the same name. The chief resources of the area are agricultural and pastoral. Population (1942) 11,850.

**ALAVA, DON MIGUEL RICARDO DE** (1770–1843), Spanish general and statesman, was a member of the assembly at Bayonne in 1808 which accepted Joseph Bonaparte as king of Spain, but shortly afterwards joined the national independent party which was fighting in alliance with the English.

He was Spanish commissary at Wellington's headquarters, and became a brigadier-general. In 1815 he was ambassador at The Hague, and was present at the battle of Waterloo. He had served at Trafalgar on the flagship of his uncle, Admiral Alava, and was said to be the only man to have been present at both Trafalgar and Waterloo. He was a deputy to the Cortes in 1820, and in 1822 fought in the militia to support the Cortes against the rebels. Alava took part in the negotiations for the restoration of Ferdinand, but was soon driven into exile. Returning to Spain after Ferdinand's death, he supported Maria Christina against Don Carlos, and was ambassador, first to London (1834) and then to Paris (1835).

He refused to take the oath to the Constitution of 1837, and died in exile at Barèges, France, in 1843.

**ÁLAVA,** one of the Basque Provinces of northern Spain. Pop. (1940) 112,876, area, 1,176 sq.mi.; density per sq.mi., 96.0. The countship of Treviño (190 sq.mi.) in S. Álava belongs to the province of Burgos. Álava (Basque *araiiar,* country set among mountains) is in the west and north-west of a district of mountain and valley, drained by the rivers Bayas and Nervión. The centre of the province is the large, fertile plain of Vitoria which continues to the west the structural trough separating the Sierra de Aralar, on the north, from the Sierra de Andia, on the south. The

Montes de Vitoria separate this plain from the lower plain of Treviño, a dried-up lake basin running east from the Ebro at Miranda and bounded on the south by the Sierras de Toloño and de Cantabria. South of these sierras lies the lowest of the three plains of the province, the Alavese Rioja, with a water-frontage on the Ebro between Haro and Logroño.

Formerly a lordship, governed by an elective *señor,* Álava was incorporated in Castile in 1332 at the request of the electoral corporation of clergy and nobility, who celebrated with Alfonso XI. of Castile the Convention of Arriaga defining administrative relations between the lordship and Castile. The modern province is in many respects transitional between the Basque country and Castile. Castilian is the ordinary language except in the north.

Rainfall is fairly regular, except in the Alavese Rioja. About a quarter of the soil of the province is cultivated, producing wheat, barley, oats and sugar beet; maize is grown on the Biscayan and Guipuzcoan border only. Agricultural methods are, for Spain, progressive, owing to the educative effect of sugar-beet cultivation, and artificial fertilizers and modern ploughs are in general use. The wine of the province is renowned, especially that of the Alavese Rioja; attacks of phylloxera have diminished the area devoted to viticulture, but many acres were replanted with American stocks. Forests of chestnut, oak and beech, controlled by the provincial authority, and rough pastures occupy almost half of the province.

Livestock includes horned cattle, sheep, goats and swine. Goats and sheep are exported to Barcelona, cattle to the market of Bilbao. Irrigation is not in use except for horticulture, but the streams are harnessed to supply electric power and light. Salt, lignite and asphalt are worked. Steel, pig-iron and puddled iron are produced, and there are manufactures of beds, furniture, railway carriages, matches, paper, sweets and woollen and cotton goods. Bread-stuffs, colonial products and machinery are largely imported. In Álava the rate of illiteracy is only 16.24%; there are secondary schools at Vitoria, the capital (pop. 1940, 44,341), which is the only town of more than 3,500 inhabitants, and good normal schools for teachers of both sexes.

The province was the scene of heavy fighting in the civil war of 1936–39 before it finally fell to the nationalist armies of Gen. Francisco Franco. (*See* BASQUE PROVINCES.)

**ALB,** a liturgical vestment of the Catholic Church. It is a sack-like tunic of white linen (Lat. *alba,* white) with narrow sleeves, and a hole for the head to pass through, and when secured round the waist by the girdle (*cingulum*) just clears the ground. Albs were originally plain, but about the 10th century the custom arose of ornamenting the borders and the cuffs of the sleeves with strips of embroidery, and this became common in the 12th century. These at first encircled the whole border; but soon it became customary to substitute for them square patches of embroidery or precious fabrics. These "parures," "apparels" or "orphreys" (Lat. *parurae, grammata, aurifrisia,* etc.) were usually four in number, one being sewn on the back and another on the front of the vestment just above the lower hem, and one on each cuff. A fifth was occasionally added just below the neck opening. In the 16th century the parures began to go out of use, and broad bands of lace soon afterwards replaced them, as in a magnificent specimen preserved at South Kensington. Apparelled albs are now only in regular use at Milan (Ambrosian Rite), and, partially in certain churches in Spain; but attempts have been made, especially in England, to revive their use.

The alb is worn by bishops, priests, deacons and subdeacons under the other eucharistic vestments at mass and at functions connected with it. It is sometimes also worn by clerics in minor orders, whose proper vestment is, however, the surplice—itself a modification of the alb. (*See* SURPLICE.) The alb is supposed to symbolize purity, and the priest, when putting it on, prays: "Make me white, O Lord," etc. In the middle ages the parures were taken to symbolize the wounds of Christ; and at Toledo the singers of the Passion on Good Friday still wear apparelled albs.

In England at the Reformation the alb went out of use with the other "Mass vestments," but was reintroduced in the ritual revival of the 19th century. It is now worn in many churches not only by the clergy but by acolytes and servers at the Communion. Where the ritual is a revival of pre-Reformation uses, these albs are frequently apparelled. (For the question of its legality *see* VESTMENTS.)

Both the alb and its name are derived from the *tunica alba,* the white tunic, which formed part of the ordinary dress of Roman citizens under the empire. The date of its definite adoption as a liturgical vestment is uncertain; at Rome—where until the 13th century it was known as the *linea* or *camisia* (*cf.* the modern Italian *camice* for alb)—it seems to have been thus used as early as the 5th century. But as late as the 9th and 10th centuries the *alba* is still an everyday as well as a liturgical garment, and we find bishops and synods forbidding priests to sing mass in the *alba* worn by them in ordinary life. (*See* Braun, p. 62.) In mediaeval inventories are sometimes found *albae,* described as red, blue or black; it is clear, however, from the descriptions of these vestments that in some cases they were actually tunicles, the confusion of terms arising from the similarity of shape (*see* DALMATIC); in other cases the colour applied to the parures, not to the albs as a whole. Silk albs appear in the inventories, but only very exceptionally.

The equivalent of the alb in the Eastern Churches is the sticharion (*στιχάριον*) of the Orthodox Church (Armenian, *shapik;* Syrian, *Kutina,* Coptic, *stoicharion* or *tuniah*). It is worn girdled by bishops and priests in all rites, by subdeacons in the Greek and Coptic rites; ungirdled, by deacons and lectors in all the rites. It is usually white for bishops and priests; for the other orders all colours, except black, may be used. Its material may be linen, wool, cotton or silk; but silk only is the rule for deacons. In the Armenian and Coptic rites the vestment is often elaborately embroidered; in the other rites the only ornament is a cross high at the back, save for bishops of the Orthodox Church, whose sticharia have two vertical red stripes (*πόταμοι,* "rivers"). As in the West, the vestment is specially associated with the Eucharist. The whole subject is exhaustively treated by Father Joseph Braun in *Die liturgische Gewandung* (Freiburg im Breisgau, 1907). (*See* also bibliography to the article VESTMENTS.)

**ALBA,** town and episcopal see, province of Cuneo, Piedmont, Italy, 42 mi. S.E. of Turin by rail. Pop. (1936) 11,072 (town), 17,308 (commune). The fine cathedral, with Gothic façade, was rebuilt in 1486. *Alba Pompeia* was probably founded by Pompeius Strabo (consul 89 B.C.) when he constructed the road from Aquae Statiellae (Acqui) to Augusta Taurinorum (Turin). The emperor Pertinax was born here. It became an episcopal see dependent on Milan in the 4th century. It is the centre of a wine-growing district.

**ALBACETE,** inland province, southeast Spain, formed in 1833 out of the northern half of Murcia. Pop. (1940), 374,472, area, 5,739 sq.mi.; density per sq.mi. 65.3. A somewhat featureless province except for the Sierra de Alcaraz in the west, Albacete continues southeast of the monotonous arid steppe land of La Mancha. Lying in the southeastern corner of the central plateau, where the border of the plateau is less clearly marked by mountains than elsewhere, the province is crossed by the main routes from Madrid both to the Valencian plain and to the southeast. The drainage is almost entirely to the Mediterranean by the rivers Júcar and Segura, but the rainfall is low and the province contributes little to the volume of these rivers except from the western sierras. In these sierras the snow lies for several months; elsewhere the climate is mild and healthy. About 55% of the province is cultivated land, of which cereals—wheat, barley, oats, rye and maize in order of importance occupy nearly half. Albacete is a stock-raising province, but the acreage devoted to wheat shows a steady rise, with much breaking-up of natural pastures and a corresponding decline in livestock. Of these, sheep, belonging to the large Manchigan breed with its all-round production, are the most important; sheep and wool are exported to Barcelona and Valencia, and cheeses to all parts of Spain.

The vine has suffered much from the repeated attacks of phyl-

loxera, and replacement with local stocks has been unsuccessful; olives are cultivated; the peaches of the Cabriel and Júcar valleys supply canning factories in Valencia. Saffron and esparto (wild) are exported, and employ much labour. There are important pine forests. Manufactures are almost confined to the spinning of hemp and the making of coarse cloth, porcelain, earthenware and cutlery. Brandy is distilled, and there is some trade in wood. Albacete, the capital (pop. 1940, 50,567), and the other important towns, Almansa and Hellin, are described separately. The railroad from Madrid to Albacete passes southwest to Chinchilla, where it bifurcates, one line going to Murcia and the other to Alicante. A large part of the province is accessible only by road. In respect of elementary education, Albacete is one of the most backward provinces. Albacete remained in loyalist hands until the end of the civil war of 1936–39.

**ALBACETE,** capital of a Spanish province, is in a fertile plain where the Balazote unites with the canal of María Cristina, which flows into the Júcar, 16 mi. to the north. Pop. (1940) 50,567 (mun., 64,222). Albacete comprises the picturesque old upper and lower town mostly erected after the city became a provincial capital in 1833. Chiefly a market-town for saffron and other agricultural produce and for live-stock, it also manufactures matches. Albacete formerly had an extensive trade in cutlery, from which it was named the Sheffield of Spain, and its daggers are still held in high repute by Spaniards.

**ALBACORE,** a large West Indian fish allied to the tunny (*q.v.*). The name is also applied to an allied species in the Pacific.

**ALBA FUCENS** (mod. *Albe*), an ancient Italian town on a lofty site (3,347ft.) at the foot of Monte Velino, 4m. N. of Avezzano. Originally a town of the Aequi, on the frontier of the Marsi, it was occupied by a Roman colony and its fortifications (*c.* 300 B.C.) persist. It lay on a hill just to the north of the Via Valeria, which was probably prolonged beyond Tibur at this very period. Later it became a regular place of detention for important State prisoners, such as Syphax of Numidia, Perseus of Macedonia, Bituitus, king of the Arverni. Its strong position made it important in the civil wars. The external walls, a circuit of about 2m., are of polygonal masonry; carefully jointed, with faces smoothed. The gates as a rule come at the end of a long, straight stretch of wall, and are placed so as to expose the right side of an attacking force. On the north there is, for a length of about 150yds., a triple line of defenses of later date, possibly added by the Roman colonists, inasmuch as both the city wall proper and the double wall thrown out in front of it are partly constructed of concrete and faced with finer polygonal masonry.

**ALBA IULIA,** a town of Transylvania, Rumania (Ger. *Karlsburg,* Hung. *Gyula-Fehérvár*), situated on the Mureș, 73m. S. of Cluj by rail. Pop. (1930) 12,457. Alba Iulia, which consists of an upper town or citadel, and a lower town, is the seat of a Roman Catholic bishop and has a fine cathedral in 11th century Romanesque, rebuilt in 1443 by John Hunyady in Gothic style. It contains among other tombs that of John Hunyady. Near the cathedral are the episcopal palace and the Batthyaneum, founded by Bishop Count Batthyány in 1794, containing a valuable library with many incunabula and old manuscripts, amongst which is one of the *Nibelungenlied,* an observatory, a collection of antiquities and of minerals. The citadel was built in 1716–35 by the emperor Charles VI. Alba Iulia occupies the site of the Roman colony *Apulum,* and many Roman relics are in the museum. The bishopric was founded in the 11th century by King Ladislaus I. (1078–95). In the 16th century the town became the residence of the independent Transylvanian princes. From this period dates the castle and also the buildings of the university, founded by Gabriel Bethlen and now used as barracks. Alba Iulia with Cluj was the traditional centre of the Rumanian national movement in Transylvania; it was here that Michael the Brave proclaimed himself prince of Transylvania, Walachia and Moldavia; here the union of Transylvania with Rumania was proclaimed in 1918 and King Ferdinand of Rumania was crowned in 1922. Alba Iulia was not in the territory ceded by Rumania to Hungary at the award of Vienna Aug. 30, 1940, during World War II.

**AL-BALADHURI** (Aḥmad ibn Yaḥya) (d. 892), native of Baghdad; one of the earliest Arab historians and the best authority for the period of the formation of the Arab empire. His chief work, *Futûh al-Buldân,* gives an account of the conquest of Arabia, Syria, Mesopotamia, Armenia, Egypt and north Africa, Spain, the Mediterranean islands, Nubia, Persia, and Media. It has been translated into English by P. K. Hitti under the title *The Origins of the Islamic State* in the *Studies in History, Economics and Public Law* series of Columbia university (1916). A second work, *Ansâb al-Ashrâf* (Lineage of Nobles), was edited by Flügel (Leipzig 1835).

**ALBA LONGA,** an ancient city in Latium, on the western edge of the Albanus Lacus, about 12m. S.E. of Rome. Ascanius is the traditional founder and said to be the oldest of Latin cities, destroyed by its daughter city of Rome, under Tullus Hostilius, to which passed the hegemony of the Latin league. It has by many topographers been placed between the Albanus Mons and the Albanus Lacus, according to the indications of Dionysius, at the monastery of Palazzolo; but the position is quite unsuitable and does not answer to Livy's description, *ab situ porrectae in dorso urbis Alba longa apellata* (it was called Alba[1] Longa because it stretched along a narrow ridge); and its site is probably on the west side of the lake, where the modern Castel Gandolfo stands. Confirmation of this may be found in Cicero's description (*Pro Milone,* 85) of the destruction of the shrines and sacred groves of Alba by the construction of Clodius's villa, in the local application of the adjective *Albanus,* and in the position of Castel Gandolfo itself. Only the necropolis remains are preserved; the earliest tombs are Villanovan (about 1100 B.C.). Later ones are 7th and 6th centuries B.C. None was found, as has been alleged, buried by a subsequent eruption of the Alban volcano. The name *Albanum,* from about 150 B.C. till the time of Constantine, meant a villa in the Alban territory. The emperors formed a single estate out of a considerable part of this district, including apparently the whole of the lake, and Domitian was especially fond of it. The imperial villa occupied the site of the present Villa Barberini at Castel Gandolfo, and considerable remains still exist. To the south a camp, with baths, an amphitheatre, a large water reservoir, etc., was constructed for the Second Parthian legion, as his bodyguard, by Septimius Severus. The camp was given up in the time of Constantine, when the *Civitas Albanensis* arose.

The lapis Albanus is a green grey volcanic stone with black and white grains in it (hence the modern name, peperino), much used for building material in Rome and its neighbourhood.

For detailed accounts *see* T. Ashby, *Jour. Phil.* xxvii. 37 (1901); G. Lugli, *Ball. Comm.* (1917–20) and *Ausonia,* ix. 211; x. 210. MacIver, *Villanovans and Early Etruscans* (Oxford, 1924); *Italy in the Iron Age* (Oxford, 1927).

**ALBAN, SAINT,** the first martyr of Britain, is said to have been born at Verulamium (St. Albans, Hertfordshire) and to have served for seven years in Rome in the army. On his return to Britain he is said by Gildas to have been put to death as a Christian during the persecution of Diocletian (*c.* 286–303), according to Bede, at St. Albans. As there is no certainty that the persecution of Diocletian extended to Britain it is possible that his martyrdom should be ascribed to that under Decius (250–251) or that of Valerian (259–260). A church was built on the place of his martyrdom, *c.* 793. A monastery was subsequently added, and around it the present town of St. Albans gradually grew up. Pope Adrian IV., who was born in the neighbourhood, conferred on the abbot of St. Alban's precedence over his fellow abbots, a right hitherto attached to the abbey of Glastonbury. St. Alban is commemorated in Catholic martyrology on June 22 and in the Church of England on June 17.

*See* U. Chevalier, *Répertoire des sources historiques* (1905), i. 95; D. Hardy, *Descriptive Catalogue* (1862), I. i. 3–34, ii. 688.

**ALBANI, DAME EMMA,** *née* LAJEUNESSE (1852–1930), celebrated Canadian singer, who was born in Chambly, Quebec,

[1]Whether Alba means "white" is very doubtful: it is more probably derived from the root Alp.

on Nov. 1, 1852. She made her first public appearance in Montreal, at the age of seven, and after studying at Milan with Lamperti (having meanwhile adopted for stage purposes the name of Albani, after that of an extinct Italian family) she made her début at Messina in Bellini's *La Sonnambula,* achieving an immediate success, which was repeated when two years later, on April 2, 1872, she made her first appearance at Covent Garden in the same opera. Thenceforward for a long period she enjoyed the widest fame and popularity, being not less esteemed as a woman than admired for her art. She married in 1878 Ernest Gye, who died in 1925, and in the same year she was accorded the D.B.E. She died in London on April 3, 1930.

*See* her *Forty Years of Song* (1911).

**ALBANI** or **ALBANO, FRANCESCO** (1578–1660), Italian painter, was born at Bologna. His first master was Denis Calvert, with whom Guido Reni was at the same time a pupil. He was soon left by Calvert entirely to the care of Guido whom he followed to the school of the Caracci. Albani opened an academy in Rome, where he resided for many years. Here he painted, after the designs of Annibal Caracci, the whole of the frescoes in the chapel of San Diego in the church of San Giacomo degli Spagnuoli. His best frescoes are those on mythological subjects, of which there is a larger number in the Verospi, now Torlonia palace. A number of his works are at Bologna, and others at Florence, the Louvre, Dresden and Leningrad.

**ALBANIA,** called in its indigenous language Shqipenija or Shqiperia ("Eagles' country"), is a state situated on the western coast of the Balkan peninsula, comprising the former Turkish province of Scutari with parts of the province of Janina and of the vilayets of Kosovo and Monastir and having an area of 10,629 sq.mi. and a population estimated at 1,200,000 in 1951. It is bounded on the west by the Adriatic sea, on the north and on the east by Yugoslavia, on the southeast by Greece and on the southwest by the Ionian sea. It became a People's republic after World War II.

**The Country.**—The Albanian lands lie athwart the mountain chain of the Dinaric Alps, but there, as contrasted with Dalmatia to the north and Greece to the south, these stand back from the sea, from which they are separated by a marshy and malarial lowland, crossed by several important rivers. The actual coast is generally low, and the shore waters are rendered turbid by the silt carried down by the rivers, thus contrasting markedly with the clear blue tint off the limestone country further north. Equally marked is the general absence of the coastal settlements so characteristic of most parts of the Mediterranean. Southward, in the region near the port of Valona, the coastal lowland disappears, and limestone hills again approach the water's edge. In this, the region anciently called Epirus, the Greek mode of life becomes visible, though Greek penetration was always limited. The Albanians have been and still are mainly mountain folk, occupying the hilly interior rather than the coastal lowland. The continuity of the mountain belt gives them a certain cultural unity, while at the same time the fact that it is broken up into a series of small natural regions, more or less isolated from each other, made the growth of a national spirit a slow process. The country has thus three essential features which go far to explain the history and characteristics of its people: because of the littoral plains it marks a definite break in the otherwise mountainous west coast of the peninsula; its elevated hinterland forms a natural refuge between the seaway to the west and the north-to-south land routes of the interior of the peninsula; within the mountain belt lie valleys and basins of considerable productivity, capable of supporting fairly dense populations. The aloofness both of the land as a whole and of its centres of settlement led to Albania's being one of the least known parts of Europe, and within the country the primitive and the modern jostle one another. Thus there are regularly scheduled air routes, wireless stations and a considerable number of roads suitable for motor traffic; but at the same time the simple wooden plow, which scarcely does more than scratch the ground, is of archaic type. The language of the country is practically unknown beyond its own borders.

**Structure and Relief.**—If Albania be first conceived as consisting of a marginal lowland, crossed by powerful perennial streams, and a complex mountainous hinterland enclosing small fertile basins, the details of the picture may be filled in as follows. To the north the Albanian Alps, built largely of massive limestones, form the outstanding feature. They have a general west-to-east direction, roughly parallel to the course of the lower Drin, below the junction of the two streams of the Black and White Drin. The Black Drin is the effluent of Lake Ochrida (Ohrid), and flows northward, draining a large part of eastern Albania, while the White Drin enters the country from Yugoslavia, flowing in a southerly direction. Below the confluence the river swings round at a sharp angle to cut through wild mountainous country, in a series of inaccessible gorges, on its way to the Adriatic. It receives a number of swift tributaries from the Albanian Alps, these also flowing in deep, steep-sided gorges, for the southern slopes of the mountains are remarkably abrupt and rocky. The result is that the actual valley of the lower Drin is not, as one might suppose, a line of access to the interior, the only practicable route from the coast to the confluence of the two headstreams running well south of the river in the hilly Mirdita region. No bridge crosses the Drin in its gorge section, and as it is too deep to be forded, the inhabitants usually cross it by swimming, supported by inflated skins.

The Albanian Alps rise to heights of 6,500–8,500 ft. above sea level, and to the northwest, where limestones predominate, they are practically a continuation of the high karst of Montenegro. To the northeast, however, other rocks, particularly Palaeozoic schists, appear and the scenery is of a different type. The steep lower slopes are thickly wooded, for the region has one of the highest mean annual rainfalls in Europe. At the higher levels, however, where considerable plateau tracts occur, there are wide summer pastures. Though in the strict sense there is no permanent snow, patches linger throughout the summer, and a very slight change in the climate would give the chain a snowcap. It was heavily glaciated during the Ice Age, and the effects of ice erosion have been to accentuate its inaccessibility and high relief. Except on their margins the mountains are virtually devoid of permanent habitations, and thus at first sight they would appear to form an admirable boundary zone. But, as has been noted by travellers, parts of the higher levels swarm with herdsmen and their flocks during the summer season, and these mountain pastures are an economic necessity to the inhabitants of the lower grounds. Great difficulties have consequently arisen in demarcating frontiers, for the line of the water parting, so often chosen as a basis, may separate a group from its pastures and thus inflict great hardship. In limestone regions, also, the water parting may be very difficult to trace.

Westward the Albanian Alps cease abruptly about 30 mi. from the Adriatic coast, giving place to quite a different type of country. Though much of it lies below 600 ft., it is not a uniform plain, and there is a belt of hills between Lake Scutari (Shkodër) and the sea. The structure is, however, perfectly clear and simple. Low limestone hills indicate that the coastal chains of Dalmatia are continued there, but two separate facts introduce a new note. The first is that depression has taken place on a much greater scale than farther north, and the second is that extensive silting has occurred, so that the sunken hill-ridges are largely submerged beneath a mantle of recent deposits. Lake Scutari itself represents an area of depression in which the filling has been incomplete. The Drin, on emerging from its gorge, swollen by the water from the Albanian Alps, has great difficulty in finding its way through the maze of its own deposits and those of its tributary the Kiri. Up to 1858 it turned southward past Alessio (Lesh) and discharged its waters by a swampy, wooded delta just south of the port called by the Italians San Giovanni de Medua and by the Albanians Shën Gjini. In 1858, during a period of high flood, it broke through to the Bojana (Buenë), the effluent of Lake Scutari, and most of its water now follows this course, the older one carrying but a small part. This caused a rise in the level of Lake Scutari, with a flooding of parts of its margins,

and also obstructed the channel of the Bojana, formerly navigable, by the silt thus poured into it. As in all such changes of river course, deserted channels and pools were left to become breeding places of mosquitoes and thus form foci of malaria.

South of this frontier zone of coastal lowland and inland mountain belt the conditions are much more complicated, both in regard to geological structure and relief. The mere fact that the Drin, after a lengthy course as the Black Drin in the interior, should cut its way through the mountains in a gorge more than 3,000 ft. deep and more than 30 mi. long is enough to suggest that there have been earth movements on a considerable scale. As far as geographical effects are concerned, however, the matter may be simply put. The course of the lower Drin marks a change in the direction of the mountain folds, associated with changes in their characters. The outer or coastal folds have sunk, and at the same time rocks from the west have been thrust over them. The inner folds have been elevated, and as a result their surface rocks, including Tertiary sandstones and Cretaceous limestones, have been for the most part worn off, exposing the deeper beds, mainly serpentines, below. These serpentines give rise to rounded land-forms, far less repellent than massive limestones, even though the elevation is considerable, a number of crests rising more than 6,500 ft. with a maximum of nearly 9,000 ft. The region has also been cut up by river action so that it is by no means uniformly high, but encloses small plains whose floors in some cases sink to only about 650 ft. above sea level.

South of the Semeni river the low ridges rise to greater heights and the limestones reappear beneath the sandstones. Still further south, beyond the Viosa river, the elevation increases to more than 6,000 ft., the limestones are fully developed, the sandstone covering disappears from the crests, though it remains in the intervening furrows, and the lowland gives place to the mountainous Epirus region, continued beyond the frontier into Greece. The vegetation undergoes a corresponding change, woods tend to disappear, and the summits are clothed with scanty herbage, again forming summer pasturages. This type of country is continued southward into Greece, and frontier lines are difficult to draw, for the whole tract is the natural home of wandering shepherds. No notable difference of elevation separates this littoral Epirus area from the mountain zone of interior Albania, but it is still possible to distinguish between the two because of the great simplicity of structure of the western folds.

From the western shores of Lake Ochrida toward the lower Drin there extends northward a mountain belt consisting of a series of blocks separated by mountain passes. This forms a central backbone repelling settlement to its margins. It is highest to the south, where also it forms a single chain, and becomes lower toward the north, where it tends to consist of rows of hills rather than of a single ridge. Finally it merges into the complex hilly country of the Mirdita, south of the lower Drin, where settlement becomes possible on the flanks of the hills as well as in the intervening valleys. Except in the extreme south, most of this central hill belt is heavily wooded, especially with beech. Above the tree limit occur the usual high pastures.

At either side of this chain lie long furrows, each consisting of a succession of basins and gorges and forming one of the most characteristic features of the country. The eastern furrow is traversed by the Black Drin and is bounded by another mountain belt on its eastern side. It might be supposed, therefore, that this mountain belt would form the eastern frontier of Albania with Yugoslavia. But this is only the case to a limited extent, for south of Dibra (Debar), on the Black Drin, the Yugoslav frontier is pushed westward and includes that town, a part of the river and the greater part of Lake Ochrida. This is but another illustration of the difficulty of drawing satisfactory frontiers in the Balkan peninsula. The difficulty here depends on the peculiar topography which is itself a result of recent earth movements. It is a characteristic feature of Macedonia that large depressed basins occur which, even when they are strung along the same river system, are separated physically from one another by mountain sills, cut through by the river in gorges. Because of these sills it happens frequently that basins belonging to separate river systems are in closer touch with one another than those linked by a single river. The Black Drin shows very markedly this feature of successive basins and gorges, the basins being largest to the south and smaller toward the north. The largest is that which is mainly submerged beneath the waters of Lake Ochrida. It is a general rule in Albania that, as compared with Macedonia, the basins are small and thus only moderately productive and not capable of supporting a dense population. At the same time the intervening gorges tend to be longer and more forbidding, and the possibility of linking effectively successive series of basins by transverse routes is much less notable. These differences have had a cumulative effect on the inhabitants of the two areas, and the present frontier, which assigns the greater part of the larger southern basins to Yugoslavia (the power which holds the adjacent section of Macedonia there) and the smaller, more northerly ones to Albania, is drawn mainly on an ethnic basis, racial distribution there being a reflection of the topography.

Some of the basins on the course of the Black Drin may be noted. The largest, as just stated, is occupied by Lake Ochrida, of which only the southwestern corner falls in Albania. There lies the settlement of Pogradets. Still further south there lies a large basin containing the town of Koritsa (Korçë), but this is best considered with the western furrow rather than with that of the Black Drin. On emerging from the lake that river passes through a heavily wooded gorge to emerge at the basin of Dibra. Though most of this basin lies in Yugoslavia, its Albanian side is also capable of settlement. A low ridge separates this basin from that of Peshkopijë (Peshkopi), farther north, and the alternation of basin and sill is continued to and even beyond the confluence of the Black and White Drin. In each basin there tends to be a market centre, but the point of importance is that the floor of the whole basin is capable of yielding cereals, especially maize and wheat, so that each forms a centre of settlement more or less isolated from its neighbours and necessarily self-sufficing.

To the west of the central mountain belt lies the second furrow, differing in several respects from that of the Drin. Though bounded on the west by the hill belt which forms the inner margin of the coastal lowland, it lacks the continuity given to its easterly counterpart by the Black Drin. A belt of highland forming the water parting between the upper Mati and a right-bank tributary of the Shkumbi divides it into a northern and a southern section, drained respectively by the upper Mati and the upper Shkumbi. North and south of this wooded and impassable highland passes permit communication with the Black Drin furrow, downstream from Dibra on the one hand and in the Lake Ochrida area on the other. The latter line is particularly important as it was followed by the Roman Via Egnatia, which passed from Durazzo (Durrës) to Elbasan (placed where the Shkumbi emerges from the hill country) and then by way of the basin traversed by that river to the shores of Lake Ochrida, which was rounded to the north. The existence of this route shows that the Shkumbi furrow is much less isolated than parts of the Drin furrow.

The headstream of the Shkumbi approaches very closely the valley of the Devoli, one of the two feeders of the Semeni river. The Devoli drains the basin of Koritsa, to the south of Lake Ochrida, and may be said to mark the region of convergence of the two furrows, the eastern and the western. Koritsa is a fairly important route centre, being connected southward through Albanian Epirus with Janina in Greek Epirus, eastward with Kastoria in Greek Macedonia, and westward by the Devoli valley with the coastal lowland as with Durazzo via Elbasan and with Valona (Vlonë). To the southwest of the Koritsa basin lies the smaller one of Kolonja, traversed by the Liumi Beratit (Usum), the other feeder of the Semeni.

**Climate and Natural Vegetation.**—The coastal lowland, together with the littoral part of the Epirus region, has the typical Mediterranean climate, with summer drought accentuated by high summer temperatures. But this type has a limited distribution. Even in the Epirus region the elevation brings changes, diminishing the heat of summer and slightly increasing its rainfall. The southern part of inner Albania, at least in the basins, shows the modified Mediterranean or Macedonian type. The summers are

hot, apparently even hotter than in the lowland, but winter frosts occur.

The natural vegetation reflects these climatic conditions. Near the coast the characteristic Mediterranean scrub or *maquis* occurs, though this has been largely cleared. It had always a somewhat limited distribution, and the most widely distributed plant association in the south is oak wood, or rather oak scrub-forest. The oaks are of the evergreen, drought-resisting type and are not only valuable as sources of fuel but also important in the low grounds as furnishing in their leaves and shoots supplementary winter fodder. Even cattle and horses eat oak leaves in Albania. To the north, with the heavier rainfall, the oak woods give place to luxuriant mixed forest, with beech as a predominant element, mingled with pines and firs. (M. I. N.; X.)

**History.**—After the division of the Roman empire, northern and southern Albania became the Byzantine provinces of Dyrrachium and Nicopolis. Overrun by the Goths in the 4th and 5th centuries, they were reconquered by Justinian in 535. In 640 northern Albania was invaded by the Serbs. The Bulgarians conquered southern Albania in 861, defeated the Serbs (893–927) and established themselves (976–1014) in the greater part of the Balkan peninsula; but in 1014 the emperor Basil II reconquered southern Albania, which remained under Byzantine rule until 1204, when Michael Comnenus, of the imperial family, founded the independent despotate of Epirus, which included southern Albania, Acarnania and Aetolia. In 1318 the despotate passed to the princes of the house of Orsini, who ruled it until 1358. Meanwhile the Sicilian kings acquired and held central Albania (1271–1368). In 1180 the Serbs had reinstalled themselves in the provinces of Scutari and Prizren, and Stephen Dushan (1331–58) included all Albania in his ephemeral empire. Large numbers of Albanians under Jin Bua Spata and Peter Liosha emigrated southward before Dushan's hordes, took Janina and Arta and penetrated as far as Acarnania and Aetolia (1358), while colonies were established in the Morea, Attica and Boeotia.

After the death of Dushan, Albania fell under the rule of native chieftains; but a Norman knight named Balsha, who had served under Dushan, established a dynasty at Scutari (1366) and induced the chieftains to co-operate under his leadership against the Serbs and Bulgarians. The power of the Balshas was, however, short-lived. At the close of the 14th century the Venetians established themselves at Durazzo, Scutari and Antivari, and in 1421 the dynasty came to an end.

**Turkish Rule.**—The advance of the Turks, who captured Janina in 1431, reunited the Albanian chieftains (1444–66) under the immortal George Kastriota of Kroia (*see* SKANDERBEG) and thereafter under the Venetians. But Kroia surrendered in 1478, Scutari in 1479, Durazzo in 1502 and Antivari and Dulcigno, the last Venetian possessions in Albania, in 1571. Many Albanians fled with their Venetian allies to Dalmatia and Italy. Although more than half the Albanian race abandoned Christianity—in the lowlands that it might enjoy equality with the Turks and in the northeastern highlands that it might obtain their support against its hereditary foes, the Slavs—Ottoman sovereignty was never effectively established, and against it the Albanians intermittently revolted. In about 1760 Mehmed Bushati, pasha of Scutari, rallied the northern clansmen and threw off Turkish suzerainty. His son, Mahmud the Black, routed three Turkish armies, but with the defeat of his grandson Mustafa in 1831 the power of the Bushati was broken. Meanwhile, in southern Albania, the able Ali Pasha of Tepelen (*see* ALI, known as ALI PASHA), by a combination of cunning and brutality, established a virtually independent state with Janina as its capital and maintained direct relations with foreign powers, but was overthrown by a Turkish army in 1822.

The revival of nationalism in Greece, Bulgaria and Serbia, coupled with the decline of the Turkish empire, induced the Albanians to seek autonomy within the empire while availing themselves of its protection until they were prepared for independence. In 1879 the Porte sought to turn Albanian nationalism to its advantage by encouraging the formation of the Albanian league, which opposed with some success the cession of Albanian territory, as provided for by the treaty of Berlin, to Montenegro and Greece. Once the league had fulfilled its purpose the Porte suppressed it, although not without much bloodshed. Then in 1908 the Albanians threw in their lot with the Young Turks—whose success was due largely to their support—in the hope that in consequence they would obtain autonomy, but the new regime proved worse than the old, and the Albanians rose in revolt against ottomanization. Throughout 1910–11 they struggled unsuccessfully, but in 1912 a general rising was successful: the vilayet of Kosovo was liberated, Monastir threatened, and in August the Turks were obliged to grant autonomy to Albania, which was to include the vilayets of Scutari, Kosovo, Janina and Monastir. But the Balkan states had envisaged the partition of Albania between them and hastened to precipitate war with Turkey. The Albanians, who wished neither to be classed as Turks and share their fate nor to facilitate the overthrow of their protectors and were without any central administration to guide them, remained neutral except at Janina and Scutari, which were vital to their national existence. On Nov. 28, 1912, Ismail Kemal Vlora, diplomatically supported by Austria-Hungary and Italy, proclaimed Albanian independence at Valona but Russia and France supported the Balkan allies, and a general European war was perhaps only averted by British arbitration. The solution of the problem was entrusted to the Conference of Ambassadors in London, which acknowledged the principle of Albanian autonomy on Dec. 20, 1912, and declared Albania an independent sovereign state on July 29, 1913. But the new state's boundaries included less than half the Albanian race.

**World War I.**—Prince William of Wied, selected by the powers to rule Albania as *mbret* (king), landed at Durazzo on March 7, 1914; but the machinations and the intrigues of various neighbouring states rendered his position untenable. Unable to extend his authority into the interior, he left Albania on Sept. 3, although he did not abdicate. Meanwhile, to resist the incorporation of southern Albania in the new state, Greece had instigated during February the constitution of a "Provisional Government of Autonomous Epirus" supported by Greeks masquerading as insurgents. The international situation prevented the powers from interfering, and anarchy continued until Greece was authorized officially to reoccupy southern Albania in the autumn. Italian troops occupied Valona in Dec. 1914, and in 1916 the whole of southern Albania, except the Koritsa (Korçë) region, which was occupied from Salonika by the French, who established an autonomous administration. Early in 1915, the Serbs and Montenegrins occupied northern and central Albania after severe fighting, but after their defeat by the Austro-Bulgarian armies these regions were occupied by the latter in 1916. Albania had no central government, although Essad Pasha posed as its president, and local policies were pursued. On June 3, 1917, Gen. Giacinto Ferrero proclaimed the independence of the whole of Albania under Italian protection, repudiating those clauses of the pact of London (1915) which provided for its partition. After the armistice the Italians occupied most of the country, the French remained at Koritsa until June 1920, the Yugoslavs occupied northeastern Albania and an inter-allied administration governed at Scutari until Feb. 1920. In Dec. 1918 a national assembly at Durazzo elected a provisional government and a delegation to the peace conference. But early in 1920 the Albanians, becoming apprehensive of the intentions of the occupying forces, held a congress at Lushnja, appointed a council of regency (representing Roman Catholics, Greek Orthodox, Sunni Moslems and Bektashis), chose Tirana as their capital and elected a more energetic government. The Italians were driven into Valona in June and withdrew from the country in August. The Yugoslavs were now asked to withdraw too but were reluctant to do so. Desultory skirmishing in the northern mountains culminated, in Nov. 1921, in a sudden Yugoslav attack designed to confront Europe with an accomplished fact, but this invasion was stopped by the intervention of the British government which convened a meeting of the council of the League of Nations (of which Albania had become a member on Dec. 17, 1920). On Nov. 9, 1921, the Conference of Ambassadors confirmed the Albanian frontiers of 1913, at the same time proclaiming that its integrity was necessary for the strategic security of Italy; but tension between Albania and its neighbours continued until minor rectifications of the

frontier were completed in 1926.

**Ahmed Zogu, Zog I.**—Ahmed Zogu, who had become minister of the interior in Albania's sixth postwar cabinet in Dec. 1921 and had added much to his reputation by his suppression of a revolt in the following March, became prime minister in Dec. 1922. Some administrative progress was made with the help of foreign advisers, but Albania sorely needed foreign financial help to develop its modest resources. Zogu's cautious policy of reform was too slow for progressive but politically immature elements, too conciliatory for the irredentists, too national for the mountain tribesmen. His resignation in Feb. 1924 did not satisfy his opponents, and widespread revolt during June drove him and his colleagues into Yugoslavia. Mgr. Fan Noli's government, which then took office, accomplished little, and Zogu was able, with Yugoslav assistance, to organize a well-equipped force with which he crossed the frontier in December and expelled Noli.

On Jan. 22, 1925, a national assembly voted the proclamation of a republic, and on Feb. 1, Zogu was elected president, the regency being abolished. By a generous attitude toward political opponents, Zogu consolidated his position, at the same time making it clear that, although grateful for Yugoslav support, he did not intend to become Yugoslavia's vassal. During Sept. 1923 negotiations with Italy for a loan were concluded and a national bank established, an Italian financial group being the principal shareholder. Relations with Greece, strained over the Graeco-Turkish exchange of populations, in which Greece sought to include the Moslem Albanians of Epirus, were improved through the mediation of the League; and a conciliatory policy toward Yugoslavia improved relations with that country, although proposals for the conclusion of a pact of friendship and security were received unfavourably in Belgrade. Zogu, although anxious to consolidate his position by obtaining support from a neighbouring power without sacrificing independence and although doubtful of the competence of the League—which had failed in his predecessor's case—to prevent his overthrow by bands from across the border, hesitated to turn to Italy, which had acquired already a commercial foothold in the country. But an insurrection in northern Albania in Nov. 1926, perhaps externally inspired, forced his hand. By the pact of Tirana, concluded on Nov. 27, Italy and Albania recognized that any disturbance directed against the established situation of Albania was opposed to their reciprocal political interest and, to safeguard it, undertook to give their mutual support and cordial collaboration.

The pact of Tirana, registered with the League of Nations in Feb. 1927, was followed by the conclusion, on Nov. 22, of a treaty of defensive alliance. Then on Sept. 1, 1928, Zogu was proclaimed Zog I (*q.v.*) king of the Albanians, while a constitution provided for a council of ministers (appointed by the king) and an elected chamber of deputies. Complete religious freedom, existing in practice, was reaffirmed.

Under King Zog, Albania made substantial progress in the educational and economic fields: schools and banks were opened, roads built, a broadcasting station established, the administration improved and the gendarmerie reorganized by an unofficial British mission under Col. W. F. Stirling and (afterward) Gen. Sir J. Percy. In the meantime Italy, under cover of its treaties with Albania, sought by all means to extend its control, pouring in advisers and technicians and a large military mission to train the army. Opposition by Albanian patriots led to the withdrawal of the Italian advisers in 1934, but the breach was patched up by a series of agreements in 1936.

**Italian Occupation and World War II.**—Italy had repeatedly proclaimed its respect for Albania's sovereignty and integrity, but the Italian general staff looked upon it as a bridgehead for the invasion of the Balkans. On April 7, 1939, Italian troops made a surprise landing in strength and quickly overcame Albanian resistance. The king fled abroad with his family, and an "Albanian National assembly" offered the crown to King Victor Emmanuel III of Italy, who accepted. The Italians built up their strength in Albania and, on Oct. 28, 1940, began their invasion of Greece. They were driven back by the Greeks, who occupied most of southern Albania, but in April 1941 Greece and Yugoslavia were overrun by the Germans, who in their turn occupied Albania (*see* WORLD WAR II). Then a native guerrilla movement under Communist direction came into being and, with the aid of small British detachments (landed in 1944) drove the axis forces from a large part of the country—simultaneously liquidating its anti-Communist opponents. Col. Gen. Enver Hoxha, commander in chief of the "Albanian Army of National Liberation," became prime minister with the ambitious Lieut. Gen. Koçi Xoxe as his ruthless minister of interior. It followed that Hoxha's "Democratic Front" won 95% of the votes in uncontested elections for a constituent assembly, which proclaimed a republic on Jan. 11, 1946.

**Communism.**—The dictatorship of Hoxha and Xoxe imposed upon Albania all the trappings and tyrannies of a Communist state subservient to the U.S.S.R. An alliance with Communist Yugoslavia was arranged notwithstanding Albanian national claims to the Kosovo region, while Albania's support of the Greek rebels under Gen. Markos Vafiades and the damage of British warships in the mined straits of Corfu further estranged it from the western powers. Albania was largely reliant upon Yugoslavia at this stage, and its continued independence could perhaps be attributed to soviet hopes that it would be admitted to the United Nations and so bring another vote to the Communist bloc. But when the Yugoslav breach with the U.S.S.R. developed in the summer of 1948 Hoxha held Albania firmly to the soviet side: Xoxe, who held other views and had almost succeeded in supplanting Hoxha, was liquidated with his chief supporters in 1949. Thereafter the U.S.S.R. tightened its grip, and though Albania's immediate value to the soviet cause was diminished by the defeat of the Greek rebels it remained a strategically important advanced base in the Mediterranean area and a thorn in the flank of Yugoslavia. Yugoslavia formally denounced its treaty of friendship with Albania in Nov. 1949; on the other hand diplomatic relations between Albania and Italy were re-established, as Albania needed a convenient source of supply to replace those lost to it by its breach with its eastern neighbour, while Italian security was best served by a friendly policy designed to reduce Albanian dependence upon the U.S.S.R. or Yugoslavia. In the meantime opponents of the Communist regime had been active, and Midhat Frasheri at last succeeded (Aug. 1949), in uniting republicans and royalists. Under Frasheri's leadership a National Committee for Free Albania was established and though Frasheri himself died in the United States two months later his movement continued to grow. (J. Sw.)

**The People.**—The inhabitants are mainly Albanians, or Shqipetars as they call themselves, with a certain admixture of Vlachs, especially in the Epirus region. But not all the Albanians live within the confines of the country. A number, estimated in the 1920s at 250,000, live in southern Italy and Sicily, where their forefathers fled from the Turks in the 15th and 16th centuries. About 50,000 are found in the United States, many emigrants leaving Epirus, a region of poverty. As in other parts of the peninsula, emigration is often temporary, the travellers returning when they have amassed a certain amount of money. In addition roughly a million Albanians live in Greek Epirus, Yugoslav Macedonia and the Kosovo Polje area outside the frontier.

The Albanians have retained their original language and, though dialects occur, the differences are said not to be so marked as to make mutual comprehension impossible (*see* ALBANIAN LANGUAGE). They are divided into Ghegs to the north of the Shkumbi line and Tosks to the south, the latter being apparently the more advanced.

About 69% of the population are Moslem, this being an effect of Turkish rule, but Albanians remained always monogamous. About 10%, mostly in the district of Scutari, are Roman Catholics, while 21%, mostly in the districts of Argyrokastro (Gjinokastër), Koritsa and Valona are Greek Orthodox. At the census of 1930 (latest taken by mid-20th century) there were 688,280 Moslems, 210,313 Greek Orthodox, 104,184 Roman Catholics and 347 others.

From the psychological standpoint the Albanians, about whose characteristics much has been written, may be said broadly to show the features common to isolated mountain folk. As is fre-

quently the case with such stocks their virtues are apt to be more highly estimated by strangers than by those with whom they come in daily contact. Theft and cold-blooded murder are not crimes, either in the estimation of the individual or of his fellows, but a breach of the plighted word or a violation of the duties of hospitality cuts a man off from his family group, and adultery is uncommon. The blood-feud or vendetta, almost inevitable in a country of such loose organization, has been in the past a scourge, and there are said to be still, at least among the Ghegs, groups which hold that the death, even the accidental death, of a kinsman can only be wiped off by the murder of the guilty person or one of his relatives. Associated with this is the strength of the *bessa* or pledge, which protects its holder absolutely. All women are protected by the *bessa,* and so also is any man accompanied by a woman. Boys under 16 years of age, ecclesiastics and generally all those incapable of bearing arms are also protected, while certain places or routes, some occupations, such as irrigation works, and certain periods confer similar rights.

**Towns.**—The principal towns, in order of importance, are (pop., 1930 census; 1949 estimates in parentheses): Tirana or Tiranë, the capital, 30,806 (40,000); Scutari or Shkodër, 29,209 (30,000); Koritsa or Korçë, 22,787 (28,000); Elbasan, 13,796 (18,000); Argyrokastro or Gjinokastër, 10,836; Berat, 10,403; Valona or Vlonë, 9,100; Durazzo or Durrës, 8,739.

## SOCIAL AND ECONOMIC CONDITIONS

**Agriculture.**—The Albanians are almost entirely dependent on the land, carrying on a characteristic combination of pastoral and agricultural occupations. Sheep form the major part of the flocks and yield cheese, which forms an important part of the diet and is exported on a considerable scale, as well as wool and skins. Goats are also reared, but the cattle are of poor breeds, yielding little milk. Oxen, with buffaloes in the swampy plains, are the plow animals. Religion excludes the thrifty pig, save among the Christian tribes, and meat of any kind is a luxury. Even the ewe's-milk cheese is too valuable to be used extensively, and the Albanians are mainly vegetarians, depending on maize bread with vegetables and whey. Horses, donkeys and mules are reared for riding and as pack animals. *See* Table I.

TABLE I.—*Livestock*
(In thousands)

| | 1933 | 1936 | 1938 | 1946* |
|---|---|---|---|---|
| Sheep | 1,500.9 | 1,675.4 | 1,573.9 | 1,548.0 |
| Goats | 928.5 | 975.0 | 923.3 | 854.0 |
| Cattle | 394.8 | 407.2 | 391.2 | 345.0 |
| Pigs | 23.5 | 24.4 | 15.3 | 35.0 |
| Horses | 66.8 | 67.8 | 54.4 | 50.0 |
| Asses | 66.6 | 68.5 | 44.6 | 40.0 |

*Estimates.

Only 10.9% of the surface is arable. The chief cereal is maize, though wheat, oats and barley are also grown. The area under crops was said to be 52% larger in 1950 than it had been in 1938. In the lower grounds all the characteristic Mediterranean fruit-trees, including olive, orange, lemon, fig, etc., can be grown, but the Albanian shows little aptitude for the more delicate operations of arboriculture. The vine is grown on a fairly large scale, especially in the south of interior Albania, and wine is made, but of a quality only fit for local use. Brandy is distilled from a variety of fruits, including mulberries, and alcoholism is said to be one of the curses of the country. Despite the presence of the mulberry, silkworm-rearing is only carried on on a small scale.

TABLE II.—*Agricultural Production*
(In thousand metric tons)

| | 1930–34 | 1935–39 | 1947* |
|---|---|---|---|
| Maize | 96.0 | 128.7 | 140.0 |
| Wheat | 43.3 | 41.0 | 54.0 |
| Oats | 11.0 | 10.3 | .... |
| Barley | 6.6 | 4.7 | .... |

*Estimates.

Rice is produced in the swampy parts of the lowland, and tobacco is fairly widespread and forms an article of export. *See* Table II.

**Mining and Industry.**—The mineral wealth of Albania, thought to be considerable, is not exactly known, no geological survey having been made. Crude petroleum production was developed by the Italians after 1934, wells being tapped at Kuçovë near Berat, at Pëkishtë southwest of Elbasan and at Selenicë and Patos, about 12 mi. N.E. of Valona. Pipe lines carried the oil to Valona and from there Italian tankers transported it to Italian refineries. Production amounted to 2,000 metric tons in 1934 and to 125,000 tons in 1939 and was believed to have reached 200,000 tons in 1942. In 1950 it was estimated at 150,000 tons; by this time Russian tankers were carrying it to Rumanian or Caucasian refineries.

There is also lignite, asphalt and bitumen on the coastal lowlands and certain interior basins. Lignite was extracted in small quantities in the region of Tirana, Tepeleni and Koritsa (4,400 metric tons in 1938). Asphalt and bitumen were worked at Selenicë, products being exported before World War II to Italy (about 10,000 tons in 1938) and from 1948 to the Soviet Union.

Of metallic minerals, pyrites, chromite, bauxite and copper ore were located: pyrites, apparently in large quantities, in the Mirdita region south of the lower Drin gorge; chromite on the western shore of Lake Ochrida and copper in the Pukë region.

Before World War II there were very few industries in Albania: a cement factory at Scutari, a brewery at Koritsa, a few small brick and tile works, several flour mills and some tobacco factories completed the list. Since World War II industrialization made considerable progress. A Lenin dam and power station were completed near Tirana in 1950, increasing tenfold the electricity supply and fourfold the water supply of the capital. In 1951 a Stalin textile works started production at Fieri: it was said that its yearly production of 20,000,000 m. of cotton fabric would satisfy all the needs of the country. A sugar refinery was also completed with a potential production in excess of the needs of the country.

The volume of mineral production in 1950 was said to be four times greater than that of 1938 and the production of manufacturing industry three times greater.

After World War II Albania concluded on Nov. 27, 1946, an agreement with Yugoslavia establishing for 30 years a customs and economic union between the two countries, and the Albanian five-year plan 1947–52 was coupled with a similar Yugoslav plan. At the end of June 1948 Albania denounced the 1946 treaty with Yugoslavia and, despite its territorial isolation, remained in the soviet-dominated area of eastern Europe. After the completion of a short-term two-year plan (1949–50), under which a total of 3,497,900,000 leks was invested in the national economy, Enver Hoxha on Sept. 24, 1951, announced a new five-year plan (1951–55). The total capital investment would amount to 21,000,000,000 leks; *i.e.,* three times as much as was already invested during the period 1946–50. The total value of the industrial and agricultural production of 1955 was expected to be 416% of that of 1938. Among the projects of this plan was an iron and steel works at Valona and a new hydroelectric power station on the Mati river with a yearly generating capacity of 100,000,000 kw.hr.

**Foreign Trade.**—Albania's trade balance between World Wars I and II was persistently adverse (*see* Table III). The country

TABLE III.—*Foreign Trade*
(In thousand gold francs)

| | 1933 | 1936 | 1938 |
|---|---|---|---|
| Imports | 15,638 | 16,778 | 22,980 |
| Exports | 5,746 | 7,435 | 9,750 |

was importing not only manufactures but also cereals and flour (16.5% in 1936–38). Chief exports were: crude petroleum (21.6% in 1938), skins (14.3%), live animals (8.3%), cheese (8.5%) and eggs (8.2%). The imports came chiefly from Italy (26% in 1938), Japan (10%), Great Britain (10%) and Germany (7%), while the exports went to Italy (62%), Greece (25%) and the United States (13%).

After World War II, U.N.R.R.A. supplies aided considerably in the country's reconstruction program. No figures of foreign trade were published after World War II.

**Communications.**—Of the four ports, only Durazzo was fully equipped; Valona, San Giovanni di Medua and Santi Quaranta

(Sarandë) were primitive. There were neither any navigable rivers nor, until World War II, any railways of normal gauge, though during World War I the Austrians had constructed narrow-gauge lines from Scutari to Durazzo, Lushna and Berat, with branches to Tirana, Elbasan and Fieri. In 1951 it was announced that a line of normal gauge was linking Durazzo with Tirana and Elbasan.

The total length of roads available for motor traffic was estimated at 2,000 mi. in 1936 and at 1,766 mi. in 1949. By Dec. 1950 there were about 500 licensed motor cars and 1,200 lorries and buses.

**Finance.**—Albania being a poor country, the state revenues between World Wars I and II were insufficient to meet the cost of administration and development, so that loans had to be raised abroad. After 1925, for political reasons, "abroad" meant Italy. Unfortunately for the protégée the protectress herself was not too rich, and the loans therefore were rather modest. In 1925 an Italian group advanced 50,000,000 gold francs, and from 1931 to 1934 the Italian state granted 10,000,000 gold francs a year. The Italian state granted a further loan of 40,000,000 in 1936 to be expended over a period of years on specified public works.

The National Bank of Albania was formed in Sept. 1925 with an almost exclusively Italian capital of 12,500,000 gold francs. The National created a currency with the Albanian gold franc (franka ara) as a unit. The franc was convertible and had a parity of 22.2215 with the gold pound sterling and 4.566 with the gold U.S. dollar.

TABLE IV.—*Summary of Budget Accounts**
(In million francs)

| | 1933–34 | 1936–37 | 1938–39 | 1939–40 | 1942–43 |
|---|---|---|---|---|---|
| Revenue . . . . . | 24.5 | 18.9 | 28.6 | 40.0 | 74.5 |
| Expenditure . . . . | 27.5 | 18.6 | 28.2 | 40.0 | 74.5 |

*Excluding expenditure on public works effected outside the budget.

The note circulation was of 11,000,000 Albanian francs between 1936 and March 1939, but after the occupation of Albania by the Italian forces inflation started. On Oct. 31, 1939, the note circulation amounted to 27,414,822 francs; there was also a coin circulation of 4,822,530 francs. By Oct. 1940 the note circulation amounted to 51,000,000 francs.

The gold cover remained constant at 7,567,000 francs from 1936 to March 1939, while the reserve in foreign exchange rose during that period from 16,300,000 francs to 45,400,000 francs. In April 1939 the Albanian franc's exchange-rate was fixed at 6.25 Italian lire.

In 1946 a new currency, the lek, was introduced. It was exchanged at the rate of five leks per franc and until June 1948 it was at par with the Yugoslav dinar. In July 1949 a state loan of 250,000,000 leks, the first loan in Albanian history, was launched. On Oct. 1, 1949, all the banknotes issued in 1947 were withdrawn and replaced by new ones, but no information was published as to the amount of the currency circulation.

Five budgets for the period 1933–43 are shown in Table IV. The state budget estimates for 1951 were: revenue 9,500,000,000 leks, expenditure 9,100,000,000 leks. Two-fifths of the expenditure, that is, 3,607,000,000 leks, was earmarked for investment in the national economy, as compared with 2,252,000,000 in 1950. The lek was by now pegged to the soviet rouble. In 1952 the exchange rate was 12.50 leks to the rouble.

**Education.**—Under the Turkish domination which prohibited teaching in the Albanian language, the Albanians remained overwhelmingly illiterate. Independent Albania, especially under King Zog I, succeeded in creating primary and secondary public instruction. In 1939 there were 663 primary schools with 38,988 male and 17,948 female pupils and 19 secondary schools with 4,810 male and 1,425 female pupils. The secondary schools included a French college at Koritsa, a teachers' college at Elbasan, schools of agriculture at Lushna and Kavaja, and a technical school at Tirana. In 1949 the number of elementary schools was estimated at 1,909 with 162,000 pupils: there were also 145 higher elementary and 20 secondary schools with a total of 19,000 pupils. A pedagogical institute was opened at Tirana in 1946.

**ALBANIA,** the ancient name of a district in the eastern Caucasus, consisting, according to Strabo (xi. 4. 1–8), of the valley of the Cyrus (Kur) and the land lying between it and the Caucasus range from Iberia to the Caspian sea. The Albani inhabited also the mountain valleys and the land to the north. (Pliny vi. 39). Dionysius of Halicarnassus quotes a tradition that the name arose because the people were the descendants of emigrants from Alba in Italy. Strabo describes them as tall, well made, and in character simple and honest. They worshipped the sun and, more particularly, the moon, the latter being perhaps identical with the great Nature Goddess of Asia Minor (*see* GREAT MOTHER OF THE GODS). Old age was held in high honour, but it was sacrilege to speak, or even to think, of the dead. The people were nomadic and lived on the abundant natural fruits of the land. In Strabo's time they appear to have been ruled by a single king. The Albani became known to the Romans during Pompey's pursuit of Mithridates the Great (65 B.C.), against which they are said to have opposed a force of 60,000 foot and 20,000 cavalry. Pompey exacted from them a nominal submission, but their independence was not seriously affected by the Romans. In the reign of Hadrian their territory was invaded by the Alani (Th. Mommsen, *Provinces of the Roman Empire,* Eng. trans. 1886), and later they fell under the Sassanid rule. They were driven finally into Armenia by the Khazars and ceased to exist as a separate people. The district subsequently suffered under the successive invasions of Huns, Varangians (who captured the chief town Barda in the 10th century), and Mongols. (*See* CAUCASUS: *History;* ARMENIA.)

**ALBANIAN LANGUAGE.** This Indo-European language is spoken in the mountainous region north of Epirus, south of Montenegro, on the eastern side of the Adriatic, by rather less than a million persons, who have kept to their ancient speech as to their ancient ways.

Apart from a few fragments of the 15th century, the oldest texts belong to the 16th and 17th centuries so that all we have is a modern version not very remote from present day speech. It is therefore difficult to construct an accurate history of the language. From what period Albanian was spoken in its present area and whence it came, cannot be stated with certainty. There is no reason for holding that it came from Thrace and it probably is the continuation of a language which from early times was spoken in this area.

Albanian preserves a number of peculiarities indicating its Indo-European origin, such as the personal pronouns, *ty,* thou; *na,* we; *ju,* you; and verbal forms as *thom,* I say; *thotë,* he says; *thomi,* we say; *thonë,* they say.

It is now modern in type. The article follows the noun. The future is expressed by a periphrasis. I will work is *do të punoj,* literally, there is a will that I should work; or *kam me punue*=I have to work, as in the French, *travaillerai.*

A few indigenous words come directly from the Indo-European stock such as, in the northern dialect (called Guègue) *dimen*=winter, plural *dîmna;* and *êmën*=name, plural *êmna.* In Tosk, the southern dialect, these nouns vary in form because *n* between vowels becomes *r,* thus *dimër, dimèra* and *emër, émera.*

The bulk of the vocabulary consists of words borrowed from foreign languages, Albanian being thus a typical Balkan speech in which words have passed from one tongue to another so that we may speak correctly of a Balkan vocabulary despite the fundamental diversity of the individual languages.

Hardly any words can be definitely traced to ancient Greek, whose influence barely reached Albania in classical days. Latin, however, has had a strong influence even from early times and Romance scholars find Latin as well as Romance loan-words. Numerals like *pes*=five, and *dhet*=ten, have an indigenous appearance; but *katrë*=four, and *qind*=one hundred, are evidently from Latin. The Latin *amicus* is *mik, canis* (dog) is *qen. Këndoj,* to recite or read comes from *canto;* as *livroj*=work, comes from *laboro;* and *kujtoj*=think, from *cogito.* Without words taken from Latin, the language would be seriously inadequate. It is a language of interest to the student, for we have a country reached by Roman civilization under the empire where the non-urban population preserved its own speech. The vocabulary is

full of Latin words while the grammar and pronunciation have remained constant to indigenous forms.

Many other influences have been at work on Albanian. Mediaeval and modern Greek have furnished many words, often by indirect routes. Other words are of Slav origin. Thus the word *lypset*="it is necessary," was borrowed from Serbian, which in turn borrowed it from Greek.

**ALBANUS LACUS** (LAGO DI ALBANO), a lake 12 mi. S.E. of Rome. It is at the bottom of an extinct crater, itself on the margin of the great crater of Albanus Mons (*q.v.*). Fed by subterranean springs, it is 560 ft. deep and the banks 400 ft. over water-level. An outlet was made in 398-397 B.C., because the Delphic Oracle said Veii could be taken only when the waters reached the sea; it is still in use and is rock-hewn, 1 mi. long, 6 ft. high and 4 ft. broad with vertical shafts and a sluice chamber. (*See* ALBA LONGA.)

**ALBANUS MONS** (mod. *Monte Cavo*), the highest point of the volcanic Alban hills, about 13m. S.E. of Rome, 3,115ft. above sea-level. It is on the inner crater rim, while Tusculum and Algidus Mons are on the earlier outer crater, about 7m. wide. Upon the Mons Albanus stood the temple of Jupiter Latiaris, where the annual festival of the Latin League was held.

Little was left of it even in the 17th century, and the charge generally brought against Cardinal York of having destroyed it to build the monastery on the summit cannot be maintained. It is very probable that it was not a large temple (of which indeed no traces have been found) but a precinct containing a number of small shrines. On the other hand, a little below the summit 16 large drums of columns, some four feet in diameter, were found, and probably belonged to some other temple. The road which ascended to the temple is still well preserved for the greater part of the way from Aricia, where it began. It was called Via Triumphalis, because minor triumphs were held on the Mons Albanus.

**ALBANY, DUKES OF.** The territorial designation of Albany was formerly given to those parts of Scotland to the north of the firths of Clyde and Forth. The title of duke of Albany was first bestowed in 1398 by King Robert III. on his brother, Robert Stewart, earl of Fife (*see* I. below); but in 1425 it became extinct. The dukedom was re-created, *c.* 1458, in favour of Alexander Stewart, "lord of Annandale and earl of March" (*see* II. below), whose son and successor (*see* III. below) left no legitimate heir. The title of duke of Albany was next bestowed upon Henry Stuart, commonly known as Lord Darnley, by Mary, queen of Scots, in 1565. From him the title passed to his son, James VI. of Scotland and I. of England. The title was by him given, at his birth, to Charles, his second son, afterwards King Charles I. By Charles II. it was again bestowed, in 1660, on James, duke of York, afterwards King James II. On July 5, 1716, Ernest Augustus, bishop of Osnaburgh (Osnabrück) (1674–1728), youngest brother of King George I., was created duke of York and Albany, the title becoming extinct on his death without heirs in 1728. On April 1, 1760, Prince Edward Augustus, younger brother of King George III., was created duke of York and Albany; he died without heirs on Sept. 17, 1767. On Nov. 29, 1784, the title of duke of York and Albany was again created in favour of Frederick, second son of George III., who died without heirs on Jan. 5, 1827. On May 24, 1881, Prince Leopold, youngest son of Queen Victoria, was made duke of Albany (*see* IV. below).

I. ROBERT STEWART (*c.* 1345–1420), duke of Albany, regent of Scotland, was a natural son of King Robert II. He was made high chamberlain of Scotland in 1382, and gained military reputation by leading several plundering expeditions into England. In 1389 he was chosen governor of Scotland by the estates; and he retained the control of affairs after his brother John became king as Robert III. in 1390. In April 1398 he was created duke of Albany; but in the following year his nephew David, duke of Rothesay, the heir to the crown, succeeded him as governor, although the duke himself was a prominent member of the advising council. Uncle and nephew soon differed, and in March 1402 the latter died in prison at Falkland. It is not certain that Albany was responsible for the imprisonment and death of Rothesay, whom the parliament declared to have died from natural causes; but the scanty evidence points in the direction of his guilt. Restored to the office of governor, the duke was chosen regent of the kingdom after the death of Robert III. in 1406, as the new king, James I., was a prisoner in London; and he took vigorous steps to prosecute the war with England, which had been renewed a few years before. He suppressed a formidable revolt led by Donald Macdonald, second lord of the isles, who claimed the earldom of Ross and was in alliance with Henry IV. of England. The duke died at Stirling Castle in Sept. 1420, and was buried in Dunfermline abbey. His son, Murdac (or Murdoch) Stewart, succeeded him as duke of Albany and regent, but the dukedom became extinct at his execution in 1425.

II. ALEXANDER STEWART (*c.* 1454–1485), duke of Albany, was the second son of James II., king of Scotland, by his wife, Mary, daughter of Arnold, duke of Gelderland. Created duke of Albany before 1458, he also received the lordship of the Isle of Man, and was afterwards captured by an English ship when journeying to Gelderland in 1468. He was soon released, and as he grew to manhood began to take part in the government and defense of Scotland, being appointed in quick succession high admiral, warden of the marches, governor of Berwick and lieutenant of the kingdom. He quarrelled with his brother, king James III., and carried on a series of intrigues with the English, who supported his pretensions to the Scottish crown. He was sentenced to death in 1483 during his absence in England. He died in France two years later.

III. JOHN STEWART (*c.* 1481–1536), duke of Albany, regent of Scotland, was born about 1481. In 1515, at the request of the Scottish Parliament, Albany came to Scotland, was inaugurated regent in July, and proceeded to organize resistance to the influence of England and of Margaret Tudor, the queen dowager, sister of Henry VIII. In August he seized the latter and her children at Stirling, and subsequently was occupied in suppressing the rebellion of the Homes, Angus (the second husband of Margaret), and James Hamilton, earl of Arran; Alexander, third lord Home, being beheaded in Oct. 1516. Albany was declared on Nov. 12 heir to the throne, and on June 6, 1517, he returned to France. In August he concluded the treaty of Rouen, by which the alliance between France and Scotland was renewed, and a daughter of Francis I. was to marry James V. Meanwhile disorders had broken out owing to the rivalry between Angus and Arran. Francis I. had secretly engaged himself to Henry VIII. not to allow Albany's departure from France, but he returned at the close of 1521 and immediately became the object of Henry VIII.'s and Wolsey's attacks. He reconciled himself temporarily with Margaret, supported her divorce from Angus, and was now accused by the English Government of harbouring schemes of marrying her himself. This was denied by the Scots, and Henry's demand for the regent's dismissal refused. War broke out in 1522, and in Sept. Albany advanced to within four miles of Carlisle with a large army. The Scots, however, showed unwillingness to fight outside their own frontiers, and Albany disbanded his troops and departed to France, leaving the borders exposed to the enemy. On Sept. 25, 1523, he once more landed in Scotland, bringing with him supplies from France and a considerable body of troops, and on Nov. 3, after an unsuccessful attack on Wark, retreated hastily, and quitted Scotland finally on May 20, 1524. On July 30 his regency was terminated by the declaration of James V. as king. Between 1530 and 1535 he acted as French ambassador in Rome, conducted Catherine de' Medici, his wife's niece, to Paris on her marriage to Henry (afterwards Henry II.) in 1534, and negotiated the marriage of James V.

The regent Albany was a singularly unfortunate commander in the field, but a successful ruler and administrator, and the Scottish court of session owed to him its institution. But he regarded himself more the subject of the king of France than of the king of Scotland, subordinated the interests of the latter state to the former, and disliked his official duties in Scotland.

IV. Leopold George Duncan Albert (1853–1884), duke of Albany, youngest son of Queen Victoria, was born on April 7, 1853. He matriculated at Christ Church, Oxford, in Nov. 1872, and pursued his favourite studies of science, art, and the modern languages. In 1876 he left the university with the honorary degree of D.C.L. On coming of age in 1874, he had been made a privy councillor and granted an annuity of £15,000. He travelled on the continent, and in 1880 visited the United States and Canada. He was a trustee of the British Museum, a bencher of Lincoln's Inn, and continued to take an active part in the promotion of education and knowledge generally. On May 24, 1881, he was created duke of Albany, earl of Clarence, and Baron Arklow. On April 27, 1882, he married Hélène Frederica Augusta, princess of Waldeck-Pyrmont, and his income was raised by parliament to £25,000. His death at Cannes on March 28, 1884, was universally regretted. He left a daughter, born in Feb. 1883, and a posthumous son, Arthur Charles Edward, born on July 19, 1884, who succeeded to the dukedom of Albany, and who, on July 30, 1900, became duke of Saxe-Coburg on the death of his uncle. He abdicated on Oct. 22, 1920.

**ALBANY, LOUISE MAXIMILIENNE CAROLINE,** Countess of (1752–1824), eldest daughter of Prince Gustavus Adolphus of Stolberg-Gedern, was born at Mons on Sept. 20, 1752. In her youth she was a canoness of Ste. Wandru at Mons, but in her twentieth year she was affianced, at the instigation of the Duke of Berwick and with the secret connivance of the French court, to Prince Charles Edward Stuart, "the Young Pretender," self-styled Count of Albany. They were married at Macerata, near Ancona, on Good Friday 1772, and went to live in the old Stuart palace at Rome and later on in Florence.

The marriage was an unhappy one, and in Dec. 1780 Louise fled to a neighbouring convent and threw herself on the protection of her brother-in-law, Henry Stuart, Cardinal York. She had already in Florence formed the acquaintance of the poet Vittorio Alfieri, who now followed her to Rome. In 1784 a legal separation between the Count and Countess of Albany was arranged, and by Charles's death in 1788 Louise found herself free. In company with Alfieri (to whom rumour said she had been secretly married) she now visited Paris and London, and was cordially received at the English court, George III. granting her an annual pension of £1,600 from the privy purse. Returning to Italy, Alfieri and the countess settled at Florence, where the poet died on Oct. 9, 1803 and was buried in the church of Santa Croce beneath Canova's vast monument erected at Louise's expense. The countess continued to reside in the house on the Lung' Arno at Florence, where she held a salon frequented by scientists and men of letters. She died on Jan. 29, 1824 and was buried in Santa Croce.

The countess bequeathed all her property to the companion of her old age, the French painter, François Xavier Fabre, who ultimately gave the greater part of his legacy to the museum of his native town of Montpellier. Two excellent portraits of the Countess of Albany and of Alfieri, painted by this artist, now hang in the Uffizi Gallery at Florence.

Bibliography.—*See* Vernon Lee, *The Countess of Albany* (1884); Marchesa Vitelleschi, *A Court in Exile.*

**ALBANY,** a municipal town in the county of Plantagenet, on Princess Royal harbour, itself an interior basin of King George sound, on the most southerly stretch of the coast, and towards the south-west corner of West Australia. The coast-line, here largely composed of granite, has sunk in recent geological times, giving rise to magnificent inlets which, however, wave action has to some extent already modified by erosion and the deposition of sand. First occupied in 1826, it was later (1889) connected by rail with the existing West Australian railway system and ultimately became the southern terminus of the Great Southern railway. Albany is 352 mi. distant from Perth by rail. Its fine and equable climate (mean annual temp.: 58.6°; mean annual rainfall: *c.* 30″) and its scenery brought it into prominence as a summer and health resort, and for long it was the port of arrival and departure for the mail steamers. A coaling station, importing Newcastle (N.S.W.) coal was established; and industries began to rise and flourish. The development of the ports of Fremantle and Bunbury; the substitution of locally mined (Collie) coal for imported coal; the loss of economic hinterland through the development of the State railway system, and the loss of passenger traffic owing to the completion of the west-east transcontinental line severely affected Albany which suffered a decline; but the development of orchards, timber and wheat in the promising southwestern region of the state offered opportunity for progress. Pop. (1933) 4,076.

**ALBANY,** a city of Georgia, U.S., 170 mi. S.E. of Atlanta, on an elevated plateau at the head of navigation on the Flint river; the county seat of Dougherty county. It is served by the Atlantic Coast Line, the Seaboard Air Line, the Central of Georgia, the Georgia Northern and the Albany Northern railroads and by Eastern Airlines. Pop. (1950) 30,987; (1940) 19,055 by federal census. It is the commercial and social centre of a region which formerly was devoted to cotton raising by Negro tenants on large plantations, but, after the boll weevil reached it about 1915, the region became the world's greatest centre for paper-shell pecan culture; there are more than 70,000 ac. in pecans within a 40-mi. radius of Albany. The region also has small farms with diversified crops. Cotton is still a profitable crop; others are peanuts, cattle, peaches, bright-leaved tobacco, sweet potatoes, watermelons, cantaloupes, hogs, poultry, berries and vegetables.

The city has diversified industries, including peanut and pecan processing plants, a meat-packing plant, farm implement plant, hosiery mills, bottling plants, candy plant and a cotton thread finishing plant.

Albany State college for Negroes is located there. Radium Springs, a resort, is 4 mi. S. of Albany. Turner air force base is located 3 mi. E.

Albany was settled in 1836; planned in 1837 by Nelson Tift from Connecticut; and incorporated in 1838. The commission-city manager form of government was adopted in 1924.

**ALBANY,** the capital of the state of New York, U.S., a city, a port of entry and the county seat of Albany county; on the west bank of the Hudson river, below the mouth of the Mohawk, 145 mi. N. of New York city; at the crossroads between Boston and Buffalo and between Montreal and New York. It is served by the New York Central, the Delaware and Hudson, the West Shore and Boston and Albany railways; by the steamboat lines on the Hudson; and is a terminus of the state barge canal system.

The area is 19.6 sq.mi. The population in 1950 was 134,382; in 1940 it was 130,577 and in 1930 127,412 by federal census.

Albany lies picturesquely on a series of hills rising sharply from the river. Fine specimens of the Dutch and later colonial architecture are still standing. The Schuyler mansion (built 1761) was dedicated in 1917 as a state historical monument. The Van Rensselaer manor house (1765) was moved in 1893 to the campus of Williams college, Williamstown, Mass. On a commanding site of 7.84 ac. stands the state capitol (300 by 400 ft.) of Maine granite, which was built (1867–98) at a cost of $25,000,000. Across the square is the beautiful colonnaded state education building, which also houses not only the state department of education, but also the state library (established 1818) of 630,000 vol. and the state museum, which has a fine collection of Indian relics. The present city hall (erected 1882), the fifth which the city has used, is a French Gothic structure of pink granite. Many of the schools, banks, hotels, clubs and churches have architectural beauty and dignity. The State Bank of Albany (1803) is probably the oldest building in America continuously used for banking purposes. There are 20 parks, of which Washington and Lincoln are the largest. A zoning ordinance was adopted in 1924 as a foundation for a comprehensive program of building and improvement. Converging railways, water routes and highways, together with a

population of 30,000,000 within a radius of 200 mi., make Albany an important distributing point. Traffic facilities were greatly improved by the New York Central's construction of the "Castleton cut-off" (opened 1924), which diverted rail traffic from the steep grades and congested trackage at Albany across a new bridge 10 mi. below the city. The same company also built a vast terminal classification yard at Selkirk west of the river, with a capacity for 20,000 cars. Albany has a municipal airport, and the deepening of the Hudson (authorized 1925), to give a 27-ft. channel from New York city, made it a very busy seaport.

The Albany port district, embracing the city of Albany, the city of Rensselaer and adjacent lands and water in the Hudson river, is in charge of a commission appointed by the governor. Ground was broken for port development in 1926. Albany has many and diverse industries. It has about 200 factories, with an aggregate output valued at more than $60,000,000 and products ranging from such staples as stoves, chemicals, textiles and paper, to billiard balls, checkers, dominoes, axle grease, paper towels, college caps and gowns and college pins. About 1,500 men are employed in printing plants. Albany is an important educational centre. The public-school system includes 28 elementary schools, vocational schools for boys and girls, junior high and high schools. The Catholic system consists of 18 parish schools (including 4 high schools), 2 academies and 2 institutions of college grade. There are several private academies. The state college for teachers (opened 1844) has an enrolment of approximately 1,500. The professional schools of Union university, which has its undergraduate college in Schenectady, are situated here; viz., the Albany College of Pharmacy (established 1881); the Albany Law school (1851); and the Albany Medical college (1839).

The Dudley observatory, founded in 1852 as the result of an abortive attempt to establish a national university in Albany, is also affiliated with Union university. Training schools for nurses are maintained by four hospitals. There are two daily papers, the *Knickerbocker News* (1842) and the *Times-Union* (1853).

Albany was probably the second permanent settlement within the borders of the 13 Colonies. Its authentic history dates from 1614, when the agents of the United New Netherland company built a small fort on Castle (now Westerlo) Island, which they occupied for three years as a trading post. In 1624 colonization was begun by the newly organized Dutch West Indian company. Eighteen families of Dutch Walloons arrived; Fort Orange was built on a hill near the present site of the capitol, and the little settlement around it became known as Beverwyck. In 1629 the Dutch government granted to Kiliaen van Rensselaer, a diamond merchant of Amsterdam, a large tract of land (ultimately 1,093 sq.mi.) on both sides of the river, centring at Fort Orange, for a patroonship. His grant was named Rensselaerswyck. The colonists he sent over were capable and industrious, and the settlement prospered. In 1652 Peter Stuyvesant, after a lengthy controversy with the director of Rensselaerswyck, established Beverwyck as an independent village. When Fort Orange was surrendered to the English (Sept. 24, 1664) Beverwyck was named Albany, one of the titles of the duke of York (afterward James II). In 1673–74 Albany again came under Dutch control for about a year, during which time it was called Willemstadt. Meanwhile the Van Rensselaer family in the Netherlands was trying to obtain from the duke of York a patent for the colony which would restore to them the ownership of the former village of Beverwyck. The application came finally to Gov. Thomas Dongan, who declined to grant it because he "did not think it convenient that the second town in the government should be in the hands of private men." The Van Rensselaers thereupon relinquished their claims to Albany, and received a patent (1685) which erected the colony of Rensselaerswyck into an English manor. On July 22, 1686, Governor Dongan granted to Albany a city charter, by which all vacant and unappropriated lands within its limits were vested in the mayor, aldermen and commonalty of the city, thus ending the jurisdictional disputes. The first mayor, appointed by the governór, was Peter Schuyler (1657–1724). In 1643, according to Father Isaac Jogues, the settlement consisted of 25 or 30 houses, built along the river; in 1695 the Rev. John Miller found 200 houses; at the first federal census (1790) the population was 3,498; by 1850 it had reached 50,763, 1910, 100,253 and in 1950, 134,382. As late as 1750 a Swedish naturalist, Peter Kahn, who wrote a vivid description of the city, found the language and manners still Dutch, though the dress was in English style. Albany became the permanent state capital in 1797.

Its strategic position at the gateway of the Iroquois country and at the head of navigation on the Hudson made Albany highly important throughout the colonial period. In 1689 the first intercolonial convention was held there, when delegates from Massachusetts Bay, Plymouth, Connecticut and New York met to treat with representatives of the five nations and to plan a system of defense. The Albany congress of 1754 was a similar and more important gathering, including commissioners also from New Hampshire, Rhode Island, Pennsylvania and Maryland, which met in anticipation of renewed hostilities with the French. It secured from the Indians assurances of their continued support, and adopted a plan (proposed by Benjamin Franklin) for "one general government" of the English Colonies for purposes of common defense. The "Albany plan," though disapproved both by the home government and by the Colonies, paved the way for the congress of 1765 and the Continental Congress of 1774. During the Revolution the British looked upon Albany as "a capital object to be subdued," and it was the objective of Gen. John Burgoyne's expedition which ended with the battle of Saratoga. In 1839 it became the centre of the "Anti-Rent War," which was precipitated by the death of the last patroon and the attempt of his heirs to collect overdue rents, and was not entirely settled until 1847. The first newspaper, the *Gazette*, was founded in 1771. The *Argus*, founded in 1813, was long the organ of the coterie of New York politicians known as the "Albany regency," and was one of the most influential Democratic papers in the country. The *Evening Journal*, founded in 1830 and edited for 35 years by Thurlow Weed, was equally influential as an organ of the Whig and later of the Republican party.

**ALBANY,** a city of Oregon, U.S., on the Willamette river, 77 mi. S. of Portland; the county seat of Linn county. It is on U.S. highways 20 and 99E and is served by the Southern Pacific and the Oregon Electric railways. The population was 10,076 in 1950 and 5,654 in 1940. Albany is an important railway centre. It manufactures furniture, boxes, sashes and doors, plywood, condensed and powdered milk. There are three sawmills, canneries, flour mills, frozen food plants, pipe and building-block manufacturing plants and meat-packing plants, a foundry, machine shops and creameries. The U.S. bureau of mines operates an important zirconium research plant there. Albany is a large turkey-shipping point and is an important seed centre. The city of Albany was settled in 1846 and incorporated as a city in 1865.

**ALBANY,** a river of Canada, rises in Lake St. Joseph in 91° 25′ W. and 50° 55′ N., and flows east-northeast into James bay; length, 610 mi.; navigable for nearly half its length, to Martin's falls. There are four Hudson's Bay company posts on its banks, including Fort Albany at its mouth. The Ogoki and Kenogami rivers are the principal tributaries.

**ALBANY CONGRESS,** a gathering of delegates from several American Colonies important for the plan which it devised for colonial union. In accordance with instructions from the British board of trade (Sept. 18, 1753), 25 delegates, representing the four New England Colonies, New York, Pennsylvania and Maryland, met at Albany, N.Y., on June 19, 1754, for the express purpose of formulating a concerted Indian policy. It was early apparent to the delegates that the question of colonial union was of even greater importance than a common Indian policy, so a committee was appointed to prepare a plan. The plan reported was chiefly the work of Benjamin Franklin and was unanimously adopted. It provided for a president-general to be appointed by the crown, and for a grand council to be elected by the colonial assemblies. This grand council was empowered to raise and pay soldiers, to build forts and to equip vessels to guard the coasts. The necessary funds were to be raised by the grand council, which was to have power to levy taxes and impose general duties. In this grant of power is seen the first suggestion of the important federal principle which underlies the entire federal structure in the United States—the right of the general govern-

ment to operate directly upon individuals. The plan was too comprehensive to suit the various colonial governments, which either rejected or failed to ratify it. It was never formally presented to the British government. As a result of this unfavourable action by the colonial governments the Albany congress failed to solve either the question of colonial union or of joint Indian policy.

**ALBANY REGENCY,** the name given to a coterie of politicians who from about 1820 to 1854 largely controlled the machinery of the Democratic party in the state of New York. The members of this group constituted the first highly effective U.S. political machine. They derived their power chiefly from their great personal influence and political sagacity. On the whole they actively opposed political corruption, though they always acted on the principle, first stated in 1833 by one of their ablest leaders (Marcy), that "to the victors belong the spoils." Among the members of this unofficial body, whose headquarters were at Albany, were Martin Van Buren, W. L. Marcy, Silas Wright and John A. Dix. About 1848 the opponents of the group began to adopt similar tactics, soon dividing the Democratic party into irreconcilable factions, and thereafter the prestige of the "regency" rapidly waned.

**ALBATEGNIUS** (MOHAMMED BEN GEBIR AL BATANI, commonly called ALBATEGNICES) (*c.* 850–929), an Arab prince and astronomer, was born at Batan in Mesopotamia. From his observations at Aracte and Damascus, where he died, he was able to correct some of Ptolemy's results, previously taken on trust. He compiled new tables of the sun and moon, long accepted as authoritative, discovered the movement of the sun's apogee, and assigned to annual precession the improved value of 55″. Perhaps independently of Aryabhatta (born at Pataliputra on the Ganges A.D. 476), he introduced the use of sines in calculation, and partially that of tangents. His principal work, *De Motu Stellarum*, was published at Nuremberg in 1537 by Melanchthon, in a blundering Latin translation by Plato Tiburtinus (*c.* 1116), annotated by Regiomontanus. A reprint appeared at Bologna in 1645. The original manuscript is preserved at the Vatican; and the Escorial library possesses in manuscript a treatise of some value by him on astronomical chronology.

*See* Houzeau, *Bibliographie astronomique,* i, 467; M. Marie, *Histoire des sciences,* ii, 113; R. Wolf, *Geschichte der Astronomie,* p. 67; Delambre, *Hist. de l'astr. au moyen âge,* ch. ii; *Phil. Trans.,* 1693 (913), where E. Halley supplies corrections to some of the observations recorded in *De Motu Stellarum.*

**ALBATROSS,** any one of some dozen species of very large sea birds related to the petrels (*q.v.*) and constituting the order Diomedeidae in the order Procellariiformes. They have heavy bodies, exceptionally long narrow wings, a short tail in all except the sooty albatrosses (*Phoebetria*), short legs placed far back, large webbed feet without hind toe and a large stout hooked bill covered with horny plates, with a tube-nostril on either side of the upper mandible. They inhabit colder oceans, often at great distances from land, nine species in lower parts of the southern hemisphere, one over cold waters off Peru and Ecuador and three in the north Pacific. The larger species (44–53 in. long) are known to sailors as gony, the smaller (28–37 in.) as mollymawk or mallemuck.

The largest species is the wandering albatross (*Diomedea exulans*), one of the two largest and most famous of flying birds, the other being the condor (*q.v.*) with smaller wing-spread but heavier body. The great wandering albatross flies over circumpolar southern seas, 30° to 60° S., and breeds on subantarctic islands. It attains a length of 53 in., yellowish bill 7 in., wing-spread 11.5 ft., and a weight of 20 lb. It is white, with faint wavy black bars on the mantle, and black tips to wings and tail. The sailor's superstition about killing an albatross was used in Coleridge's *Rime of the Ancient Mariner.* In regions of strong winds or gales albatrosses do not flap their wings but glide for hours low over rolling seas, settling on the water to feed on cuttlefish and squid, taking flight by fully extending their wings and running against the wind. With salt pork as bait, they are caught on hook and line, cannot take flight from the deck, and become seasick with the roll of the ship. They rarely approach land, and breed on remote oceanic islands, rocky and inaccessible or low of coral sand. Some species have elaborate courtship performances. A single egg, dull white finely speckled near the larger end with brown, is laid December to February (August to January in all others but one) in a depression on the ground, or on trampled grass and debris; both parents incubate the egg, two to three months in different species, and care for the young, which is fed for many months on regurgitated food. The great royal albatross (*D. epomophora*), of Tierra del Fuego and islands south of New Zealand, has bulbous nostril-tubes and is only slightly smaller and whiter than the wandering albatross.

Others of cold southern seas include the white-capped albatross (*D. cauta*), breeding in the southwest Pacific from southeastern Australia to the Chatham Islands and ranging east to western and southeastern South America and west to the Cape of Good Hope; and the black-browed albatross (*D. melanophris*), circumpolar to the pack-ice, breeding on subantarctic islands. Ranging with the latter is the gray-headed albatross (*D. chrysostoma*), slightly further north the yellow-nosed albatross (*D. chlororhynchos*), head white, of the south Atlantic and Indian Oceans, and Buller's albatross (*D. bulleri*), with gray head and white fore-cap, of the south Pacific; the last three have a yellow stripe along the top of the black bill and are known as yellow-nosed mollymawks.

Of the three albatrosses that breed on islands west of Hawaii, and range far over the north Pacific and southwestward, the largest is the short-tailed albatross (*D. albatrus*), 37 in., with pink bill and pale feet, the only white-bodied north Pacific species, now nearly extinct. The Laysan albatross (*D. immutabilis*), length 32 in. and wing-spread 6 ft. 8 in., with sooty mantle and pink feet, is famous for its courtship dance. The commoner, slightly smaller black-footed albatross (*D. nigripes*), 28 in., is sooty brown with whitish around the base of the bill. The Galapagos or waved albatross (*D. irrorata*), mainly dark with white head and neck, breeds in May and June on Hood Island and feeds over the cold Humboldt current off Peru.

Two southern species (*Phoebetria*) have dark plumage, an incomplete white eye-ring and a longer wedge-shaped tail. They are more slender, graceful and skilled in flight. The sooty albatross (*P. fusca*), mainly sooty brown, breeds in the cool southeastern Atlantic, and ranges to South America and the Australian seas; the gray-mantled sooty albatross (*P. palpebrata*), pearl gray with darker head, wings and tail, is circumpolar south of 35° S., and northward with the cold waters along western South America. (G. F. Ss.)

**ALBAY** (now Legaspi), a municipality (with administrative centre and 19 *barrios* or districts) and capital of the province of Albay, Luzon, P.I., near an inlet on the west shore of the gulf of Albay, about 200 mi. by road S.E. of Manila. Pop. (1939), 41,468, of whom 21,015 were males and 87 were white.

The municipality lies on level ground near the south base of Mayon volcano (7,943 ft., surmounted by the most perfect known volcanic cone) from which it is sheltered by the Linguin hills. Formally established in 1636 under the name of Albay, it had by 1649 a population of about 1,200, a Roman Catholic church, a fortified structure and a partly completed wall. Destructive eruptions of the volcano occurred from time to time, notably in Feb. 1815, when much of the centre and surrounding district was submerged and about 1,200 inhabitants were killed. There was another less violent eruption in 1897. The town was partly destroyed by insurgents in 1900, but civil government under the United States was established in the following year. It was a point of debarkation for the Japanese forces which invaded Luzon and advanced on Manila from the south in Dec. 1941. Under the stable U.S. regime the municipality grew steadily in importance and in the range of its industries. It has railway and steamship connections with the important Philippine towns, and automobile roads lead to various parts of the province as well as to Manila;

it is the centre and exporting point of one of the most productive regions of abacá (Manila hemp). Other native fibres are produced and woven into fabrics for export as well as for home consumption. Palay (rice), maize (corn), copra and sugar are also grown. Of the inhabitants aged 6 to 19, inclusive, 33.1% in 1939 attended school, while 54.3% of the population 10 years old and over was literate. The municipalities of Albay and Legaspi were merged in 1907, and the name was changed to Legaspi in 1925. The vernacular is Bikol. The number of parcels of land declared for taxation in 1938 was 9,039 and the number of owners, 6,294.

**ALBEDO** (from Lat. *albus*, white), "whiteness," a word used principally in astronomy for the measure of reflecting power. A body shining by reflected light is said to have albedo ½ if it reflects (or scatters outwards) half the light incident on it. The albedo for visual light of the cloud-covered planets (Venus, Jupiter, Saturn, Uranus, Neptune) ranges from 0.56 to 0.73; of the earth 0.44; Mars 0.15; Moon 0.07. (*See* H. N. Russell, *Astrophysical Journal*, vol. xliii. p. 173.)

**ALBEMARLE, WILLIAM DE FORS** or **DE FORTIBUS,** EARL OF (d. 1242), was a great-grandson of King Stephen and a son-in-law of William of Blois. He is described by Bishop Stubbs as a "feudal adventurer of the worst type." He was one of the executors of Magna Carta, but frequently changed sides in the civil war that followed, his general aim being to revive the power of the feudal barons. In 1221, 1222 and 1223 he was in revolt, although in each case he was compelled to submit, and was twice excommunicated. He died at sea on his way to the Holy Land on March 26, 1242.

ALBEMARLE, GEORGE MONK OR MONCK, 1st duke of. *See* MONK.

ALBEMARLE, ARNOLD JOOST VAN KEPPEL, 1st earl of (1669–1718), was born in Holland, and accompanied William III. to England in 1688. He was created earl of Albemarle in 1697. The confidant of the king, he returned to Holland at his death, and became a general of horse in the Dutch army. He joined the allied forces in 1703, fought at Ramillies, Oudenarde, and the siege of Lille. He led Marlborough's second line in 1711.

ALBEMARLE, GEORGE THOMAS KEPPEL, 6th earl of (1799–1891), British general, served in the campaign of Waterloo. He was aide-de-camp to the marquess of Hastings in India, returning home in 1823 by way of Persia and St. Petersburg (now Leningrad). He wrote a narrative of the journey, *Journey from India to England* (1825). Gen. Keppel sat in the first reformed parliament as a member for East Norfolk (1832–35) and for Lymington (1847–49). He succeeded to the title in 1851.

*See* his *Fifty Years of My Life* (1875).

**ALBEMARLE AND CHESAPEAKE CANAL,** in the United States, connecting Norfolk, Va., with Currituck Sound, N.C., is a portion of the inland navigation between New York, Philadelphia, Baltimore and North Carolina and is connected with the Chesapeake and Delaware and Raritan canals. It is 11.2 mi. long, 80 ft. wide, 12 ft. in depth and has one lock. Its capacity is steamers of approximately 800 tons, drawing 11 ft. of water. The canal was opened in 1860, and the cost of construction was $1,641,363.

**ALBEMARLE SOUND,** a large inlet on the Atlantic coast of North Carolina, U.S.A. It has an east and west direction extending along the 36th parallel of north latitude, a length of about 50 mi., and a breadth of from 5 to 15 miles. The depth varies from a few feet to 20 ft. or more. Albemarle is separated from the Atlantic by a long narrow barrier beach. From the northeast end of the Albemarle the long, narrow arm called Currituck sound extends northward about 40 mi. to and beyond the Virginia border. On the southeast Albemarle is connected with Pamlico sound by Croatan sound, and also by a narrower channel, Roanoke sound, separated from the former by Roanoke Island. From Albemarle sound project many bay-like arms, commonly called rivers, because they serve as the mouths of streams; but they are true bays, having a breadth of several miles and a depth about equal to that of the sound. Roanoke river (*q.v.*) is the most important stream emptying into it. Albemarle is connected with Norfolk, Va., harbour partly by natural and partly by artificial waterways (Dismal Swamp canal and the Albemarle and Chesapeake canal), thus forming an important link in the great inland waterway extending from Massachusetts to Beaufort, North Carolina.

**ALBENGA,** town and episcopal see, province of Savona, Italy, on the northwest coast of the Gulf of Genoa, 52½ mi. S.W. of Genoa by rail. Pop. (1936), 5,848 (town), 10,698 (commune). Albenga is the ancient *Album Ingaunum* or *Albingaunum,* the chief town of the Ingauni, whose territory reached as far as Genoa. An inscription records the restoration of the walls, forum, harbour, etc., by Constantius A.D. 354. To the east is a well-preserved Roman bridge, Ponte Lungo, nearly 500 ft. long and 11½ ft. wide, with 10 arches, each with a span of 37 ft. To the south is a conspicuous rectangular pillar, 27 ft. high, probably marking a tomb. A good brick Gothic cathedral has an interesting octagonal baptistery (8th or 9th century).

**ALBENIZ, ISAAC** (1860–1909), Spanish pianist and prolific composer, who only towards the close of his career found his true métier and wrote the works which give him his chief claim to remembrance. These were his brilliant and fascinating pianoforte pieces, such as the suite *Iberia,* reproducing the rhythms and other characteristic features of Spanish popular music. He wrote also a number of works for the stage, including a comic opera, *The Magic Opal,* produced in London, and a more ambitious work, *Pepita Jiménez,* but these were of less account.

**ALBERONI, GIULIO** (1664–1752), Spanish-Italian cardinal and statesman, the son of a gardener, born near Piacenza, probably at the village of Fiorenzuola. He took priest's orders, and found his way to Rome in attendance on the son of a bishop. During the War of the Spanish Succession Alberoni rendered substantial services to the Duke of Vendôme, commander of the French forces in Italy, and in 1711 he followed him into Spain as his secretary. Two years later Alberoni was appointed consular agent for Parma at the court of Philip V. of Spain, and helped to arrange the king's marriage with Elizabeth Farnese of Parma, by whose influence he was made a member of the king's council, bishop of Malaga, and in 1715 prime minister. Alberoni's foreign policy was to undo the work of the Treaty of Utrecht. He desired to gain the succession of Elizabeth to Parma and Piacenza, then in the hands of Austria. To this end he made hurried attempts to reform the administration and the military and financial organization of Spain. But the impatience of Elizabeth left him no time to mature his plans. In 1718 Alberoni equipped a small expedition to help the Scottish Jacobites against George II, but the fleet was wrecked on its way from Cadiz. The Spanish ambitions in Italy led to the Quadruple Alliance of England, France, Austria and Holland, all of which needed a long period of peace for recovery from the last war, and after the landing in 1718 of Spanish troops at Palermo, French armies and English ships invaded Spain. After the Spanish collapse Alberoni was exiled, and went to Italy, where he took refuge in the Apennines, Pope Clement XI, who was his bitter enemy, having ordered his arrest. On the latter's death Alberoni appeared at the Conclave and took part in the election of Innocent XIII (1721), after which he was imprisoned for a time by the Pope, at Spain's demand. At the next election, he was himself proposed for the papal chair, and secured 10 votes at the Conclave which elected Benedict XIII. He died on June 16, 1752. Alberoni left a number of manuscripts, but the genuineness of the *Political Testament* published under his name at Lausanne in 1753 has been questioned.

An *Histoire du Cardinal Alberoni* up to 1719 was published by Jean Rousset de Missy at The Hague in 1719. A laudatory life, *Storia del Cardinale Giulio Alberoni,* was published by Stefano Bersani, a priest educated at his college, at Piacenza, in 1861. *Giulio Alberoni e il suo secolo,* by Giovanni Bianchi (1901), is briefer and more critical. *See* also *Lettres intimes de J. Alberoni,* edited by M. E. Bourgeois (1892).

**ALBERT I** (1875–1934), king of the Belgians, was born at Brussels, April 8, 1875, the younger son of Philip, count of Flanders (1837–1905), who was a brother of Leopold II, and Princess Marie of Hohenzollern. The other children of this marriage were Baldwin (b. 1869), Henriette, afterward duchess of Vendôme (1870–1948), a daughter who died in infancy and Josephine, afterward Princess Charles of Hohenzollern (b. 1872).

The premature death of Prince Leopold, only son of Leopold II, on Jan. 22, 1869, made Prince Baldwin heir presumptive to the Belgian crown, but on his death on Jan. 23, 1891, Prince Albert

became next in the line of succession. He was carefully educated, and showed a marked taste for engineering and mechanics, studying both naval and aerial construction. He received his training in military matters at the École Militaire under Gen. Jungblut, and also became a thorough sportsman, taking much interest in mountaineering and later in aviation. He served as an officer in the Grenadier regiment. On Oct. 2, 1900 he was married at Munich to Elisabeth (b. July 25, 1876), second daughter of Duke Charles Theodore of Bavaria. Three children were born of this marriage: Leopold, duke of Brabant (b. Nov. 3, 1901); Charles, count of Flanders (b. Oct. 10, 1903) and Marie José (b. Aug. 4, 1906). *See* LEOPOLD III.

Prince Albert also travelled widely, paying a visit to America in 1898, and in 1908 visiting England in order to study naval construction. In April 1909 he went to the Belgian Congo. Starting from the Cape, he visited the Cape province and the Transvaal, going from there to Elisabethville. Thence he traversed the Katanga mineral region and followed the course of the Congo to its mouth. He returned to Belgium in August, and three months later King Leopold died.

On Dec. 23, 1909 Prince Albert took the oath of fidelity to the Belgian constitution, and became king under the name of Albert I. In his speech from the throne, the king emphasized his care for the people's welfare in the words: "Our prosperity depends upon the prosperity of the masses." He occupied himself more especially with the organization of the army, and in May 1913 gave his assent to the law which was designed to secure for Belgium an army of 350,000 men. He also interested himself in various social and legal reforms, while his scientific tastes did not prevent him becoming a friend of art and literature. The economist Waxweiler, the poet Verhaeren and the painter Laermans were on friendly terms with the royal family, the latter receiving personal attention from the queen when he was threatened with the loss of his sight.

Albert was anxious to preserve friendly relations with neighbouring States, and after 1910 paid official visits both to Berlin and Paris. On Nov. 5 and 6, 1913, the king, who had been appointed honorary colonel of the regiment of Hanover Dragoons, visited Germany for the second time. At a reception in Potsdam, the Emperor William II. and Gen. von Moltke informed him that they considered war with France imminent. The king gave warning of this to the French ambassador in Berlin through his own minister plenipotentiary, Baron Beyens. On July 31, 1914, when the European crisis came to a head, the king wrote a personal letter to the German emperor, reminding him of the respect due to Belgian neutrality. Germany replied by the ultimatum of Aug. 2, which in turn was answered by a *fin de non recevoir* and hostilities began. The king took command of the troops and established his headquarters first at Louvain and afterwards at Antwerp. He directed in person the first advance from Antwerp towards Louvain, which was intended to relieve the French and British armies engaged with the forces of Kluck and Bülow. After the fall of Antwerp, the king and queen sent their children to England, while they themselves accompanied the retreating army; when it came to a halt on the Yser they took up their residence at Furnes. From Oct. 17 to 24 the Belgian army, under the king's command, withstood the German invasion without any Allied assistance. During the whole of the war he remained with the troops, having his headquarters at La Panne, where he was exposed to the risk of enemy bombardments. He made continual visits to the front-line trenches, and even surveyed the enemy's lines from an aeroplane. The queen remained with him, acting as a nurse in the Hôpital de l'Océan at La Panne. She also interested herself deeply in the welfare of the soldiers in the trenches, and superintended the establishment of canteens and aid posts. Prince Leopold, King Albert's elder son, lived by his father's wish, the life of a simple soldier in the 12th Regiment.

When the general offensive of Oct. 1918 was undertaken, Albert was appointed commander of the northern army groups, consisting of both Belgians and French, which captured the forest of Houthulst, "the Flandernstellung," Thourout, Ostend and Bruges, and forced the passage of the Lys. On Nov. 11, 1918 the king and queen made their entry into Ghent, and on Nov. 22 into Brussels, being received with enormous enthusiasm. Even before the signing of the Armistice the king had summoned at Lophem a number of politicians and had arranged a new government containing representatives of the three more important Belgian political parties. After a triumphant reception by parliament, the king made a speech from the throne, in which he urged that all parties should work together for national reconstruction, while, addressing himself to the Allies, he asked for the abolition of Belgian neutrality and of the treaties of 1839 which had left Belgium open to invasion. After the Armistice, King Albert declined the augmentation of his civil list. He occupied himself actively with the improvement of conditions in his country, visiting the devastated areas, and contributing considerable sums to "King Albert's Fund," which was devoted to providing temporary shelter for sufferers from the war.

The king in person presided at the Colonial Congresses of 1920 and 1926 and made important speeches on those occasions. He was actively interested in the development of the Belgian mercantile marine. As before the war, he continued to support the intellectual development of his country. After the war he made official visits to the State universities of Ghent and Liége. In Jan. 1926 King Albert, who had been given honorary degrees by many universities, was elected a member of the *Institut de France*. His constant solicitude for the welfare of his people was shown during the floods which ravaged Belgium in Dec. 1925. On Feb. 17, 1934, while rock-climbing near Namur, King Albert fell and was killed. (*See* BELGIUM.)

**ALBERT 1.** (*c.* 1250–1308), German king and duke of Austria, eldest son of King Rudolph I., was invested with the duchies of Austria and Styria in 1282. On Rudolph's death in 1291 Albert was obliged to acquiesce in the election of Adolph of Nassau as German king, but in 1298 he mustered sufficient allies to enable him to defeat Adolph at Göllheim, near Worms, was elected king at Frankfort on July 27, and crowned at Aix on Aug. 24. Pope Boniface VIII. declined to recognize him until 1303 when Albert admitted the right of the pope to bestow the imperial crown and promised that none of his sons should be elected king without papal consent. In 1306 he secured the crown of Bohemia for his son Rudolph, but tried in vain to impose his own claims on Thuringia in 1307. His action in abolishing all tolls established on the Rhine since 1250, led to the formation of a league against him by the Rhenish archbishops and the count palatine of the Rhine; but aided by the towns, he soon crushed the rising. He was on the way to suppress a revolt in Suabia when he was murdered on May 1, 1308, at Windisch on the Reuss, by his nephew John, afterwards called the "Parricide," whom he had deprived of his inheritance.

Although a hard, stern man, he had a keen sense of justice when his selfish interests were not involved, and few of the German kings possessed so practical an intelligence. He encouraged the cities, and not content with issuing proclamations against private war, formed alliances with the princes in order to enforce his decrees. The serfs, whose wrongs seldom attracted notice in an age indifferent to the claims of common humanity, found a friend in this severe monarch, and he protected even the despised and persecuted Jews. The stories of his cruelty and oppression in the Swiss cantons first appear in the 16th century, and are now regarded as legendary.

*See* A. L. J. Michelsen, *Die Landgrafschaft Thüringen unter den Königen Adolf, Albrecht, und Heinrich VII.* (Jena, 1860); G. Droysen, *Albrechts I. Bemühungen um die Nachfolge im Reich* (Leipzig, 1862); J. F. A. Mücke, *Albrecht I. von Habsburg* (Gotha, 1866).

**ALBERT II.** (1397–1439), German king, king of Bohemia and Hungary, and (as Albert V.) duke of Austria, was born on Aug. 10, 1397, the son of Albert IV. of Habsburg, duke of Austria

He succeeded to the duchy of Austria on his father's death in 1404, and in 1438 succeeded his father-in-law, Sigismund, as German king, though he does not appear to have sought election.

He was crowned king of Hungary and of Bohemia but was unable to obtain possession of the latter country. His reign, which lasted less than two years, was spent in the defence of Hungary against the Turks. He died at Langendorf on Oct. 27, 1439. Albert was an energetic and warlike prince, whose short reign gave great promise of usefulness for Germany.

*See* W. Altmann, *Die Wahl Albrecht II. zum römischen Könige* (1886).

**ALBERT, FREDERICK AUGUSTUS** (1828–1902), king of Saxony, was born April 23, 1828, being the eldest son of Prince John, who succeeded to the throne in 1854. In 1849 he served as a captain in the campaign of Schleswig-Holstein against the Danes. When the war of 1866 broke out, the crown prince was placed in command of the Saxon forces opposing the Prussian army of Prince Frederick Charles. No attempt was made to defend Saxony; the Saxons fell back into Bohemia and effected a junction with the Austrians. They took a prominent part in the battles by which the Prussians forced the line of the Iser and in the battle of Gitchin. The crown prince, however, succeeded in effecting the retreat in good order, and in the decisive battle of Koeniggraetz (*see* SEVEN WEEKS' WAR) he held the extreme left of the Austrian position with great tenacity. After peace was made and Saxony had entered the North German confederation, he was placed in command of the Saxon army, which had now become the XII. Army Corps of the North German army. He was a firm adherent of the Prussian alliance.

On the outbreak of war in 1870 he again commanded the Saxons, who formed the extreme left of the German army, at Gravelotte, and with the Prussian Guard carried out the attack on St. Privat, the final and decisive action in the battle. In the march towards Paris the crown prince was given a separate command over the 4th army (army of the Meuse) consisting of the Saxons, the Prussian Guard corps, and the 4th (Prussian Saxony) corps. He took a leading part in the operations which preceded the battle of Sedan, the 4th army being the pivot on which the whole army wheeled round in pursuit of MacMahon; and the actions of Buzancy and Beaumont on Aug. 29 and 30 were fought under his direction; in the battle of Sedan itself, with the troops under his orders, he carried out the envelopment of the French on the east and north. Albert had won the complete confidence of the army, and during the siege of Paris his troops formed the north-east section of the investing force. After the armistice he was left in command of the German army of occupation, a position which he held till the fall of the Commune.

On the conclusion of peace he was made an inspector-general of the army and field-marshal. On the death of his father on Oct. 29, 1873, he succeeded to the throne. The king devoted himself mainly to military affairs, in which his advice and experience were of the greatest value to the German army in general. In 1897 he was appointed arbitrator between the claimants for the principality of Lippe. King Albert married in 1853 Carola, daughter of Prince Gustavus of Vasa, and granddaughter of the last king of Sweden of the house of Holstein. He died June 10, 1902.

**ALBERT** (1522–1557), prince of Bayreuth, surnamed THE WARLIKE, and also ALCIBIADES, was a member of the Franconian branch of the Hohenzollern family. His restless and turbulent nature marked him out for a military career; and having collected a small band of soldiers, he assisted the emperor Charles V. in his war with France in 1543. Sharing in the attack on the Saxon electorate, Albert was taken prisoner at Rochlitz in March 1547 by John Frederick, elector of Saxony, but was released as a result of the emperor's victory at Mühlberg in the succeeding April. He then followed the fortunes of his friend Maurice, the new elector of Saxony, deserted Charles, and joined the league which proposed to overthrow the emperor by an alliance with Henry II. of France. Having extorted a large sum of money from the burghers of Nuremberg, he quarrelled with his supporter, the French king, and offered his services to the emperor. Charles, anxious to secure such a famous fighter, gladly assented to Albert's demands and gave the imperial sanction to his possession of the lands taken from the bishops of Würzburg and Bamberg. After Albert had been placed under the imperial ban in Dec. 1553 on account of his depredations in Franconia, he was defeated by Henry II., duke of Brunswick, and compelled to fly to France. He there entered the service of Henry II., and had undertaken a campaign to regain his lands when he died at Pforzheim Jan. 8, 1557.

**ALBERT, PRINCE CONSORT OF ENGLAND** (1819–1861), b. at Rosenau Aug. 26, 1819. Francis Charles Augustus Albert Emmanuel was the second son of the hereditary duke of Saxe-Coburg-Gotha (belonging to the Ernestine or elder branch of the royal family of Saxony) by his first wife, the Princess Louise of Saxe-Gotha-Altenburg (d. 1831), from whom the duke was separated in 1824. His father's sister married the duke of Kent, and her daughter, afterwards Queen Victoria of England, was thus his first cousin. They were born in the same year. Albert and his elder brother, Ernest, were educated privately and at the University of Bonn. There Prince Albert studied natural science, political economy, and philosophy; he diligently cultivated music and painting, and excelled in gymnastic exercises, especially in fencing.

The idea of a marriage between him and his cousin Victoria had always been cherished by their uncle, King Leopold I. of Belgium, and in May 1836 the duke of Saxe-Coburg-Gotha and his two sons paid a visit to the duchess of Kent and her daughter at Kensington Palace. The visit was by no means to the taste of King William IV., who disapproved of the match and favoured Prince Alexander of Orange. But Leopold's plan was known to Princess Victoria, and William's objections were fruitless. Princess Victoria, writing to her uncle Leopold (May 23, 1836) said that Albert was "extremely handsome," and (June 7) thanked him for the "prospect of great happiness you have contributed to give me in the person of dear Albert. He possesses every quality that could be desired to render me perfectly happy." In the winter of 1838–39 the prince travelled in Italy, accompanied by Baron Stockmar, the Queen's confidential adviser, formerly Leopold's doctor and private secretary. On Oct. 10, 1839, he and Ernest went again to England to visit the Queen, with the object of finally settling the marriage. The betrothal took place on Oct. 15, and on Feb. 10, 1840 the marriage was celebrated at the chapel-royal, St. James's.

The public life of the Prince Consort cannot be separated from that of the Queen, and it is unnecessary here to repeat such details as are given in the article (*see* VICTORIA, ALEXANDRINA). The prejudice against him, on account of what was regarded as his undue influence in politics, was never fully dissipated till after his death. His co-operation with the Queen in dealing with the political responsibilities which devolved upon the sovereign represented an amount of conscientious and self-sacrificing labour which cannot easily be exaggerated; and his wisdom in council could only be realized, outside a very small circle, when in later years the materials for the history of that time became accessible. He was indeed a man of cultured and liberal ideas, well qualified to take the lead in many reforms which the England of that day sorely needed. He was specially interested in endeavours to secure the more perfect application of science and art to manufacturing industry.

The Great Exhibition of 1851 originated in a suggestion he made at a meeting of the Society of Arts, and owed the greater part of its success to his intelligent and unwearied efforts. He had to work for its realization against an extraordinary outburst of angry expostulations. Every stage in his project was combated. In the House of Peers, Lord Brougham denied the right of the Crown to hold the exhibition in Hyde Park; in the Commons, Colonel Sibthorp prophesied that England would be overrun with foreign rogues and revolutionists, who would subvert the morals of the people, filch their trade secrets from them, and destroy their faith and loyalty towards their religion and their sovereign.

Prince Albert was president of the exhibition commission, and every post brought him abusive letters, accusing him, as a foreigner, of being intent upon the corruption of England. He was not the man to be balked by talk of this kind, but quietly persevered, looking always to the probability that the manufacturing power of Great Britain would be quickened by bringing the best manufactured products of foreign countries under the eyes of the mechanics and artisans. The exhibition was opened by the Queen on May 1, 1851, and was a colossal success; and the realized surplus of £150,000 went to establish and endow the South Kensington Museum (afterwards renamed "Victoria and Albert") and to purchase land in that neighbourhood.

THE ALBERT MEMORIAL IN LONDON, BEGUN IN 1872 AND COMPLETED IN 1876, ERECTED IN MEMORY OF ALBERT, PRINCE CONSORT OF ENGLAND

Similar institutions, on a smaller scale but with a kindred aim, always found in him warm advocacy and substantial support. It was chiefly at meetings in connection with these that he found occasion for the delivery of addresses characterized by profound thought and comprehensiveness of view, a collection of which was published in 1857. One of his best speeches is the inaugural address which he delivered as president of the British Association for the Advancement of Science when it met at Aberdeen in 1859. The education of his family and the management of his domestic affairs furnished the Prince with another very important sphere of action, in which he employed himself with conscientious devotion.

As the Prince became better known, public mistrust began to give way. In 1847, but only after a significantly keen contest with Earl Powis, he was elected chancellor of Cambridge University; and he was soon afterwards appointed master of Trinity House. In June 1857 the formal title of Prince Consort was conferred upon him by letters patent, in order to settle certain difficulties as to precedence that had been raised at foreign courts.

But in the full career of his usefulness he was cut off. During the autumn of 1861 he was busy with the arrangements for the projected international exhibition, and it was just after returning from one of the meetings in connection with it that he was seized with his last illness. Beginning at the end of November with what appeared to be influenza, it proved to be an attack of typhoid fever, and, congestion of the lungs supervening, he died on Dec. 14. The grief of the Queen was overwhelming and the sympathy of the whole nation marked a revulsion of feeling about the Prince himself which was not devoid of compunction for earlier want of appreciation. The magnificent mausoleum at Frogmore, in which his remains were finally deposited, was erected at the expense of the Queen and the Royal Family; and many public monuments to "Albert the Good" were erected all over the country, the most notable being the Albert Hall (1867) and the Albert Memorial (1876) in London. His name was also commemorated in the Queen's institution of the Albert medal (1866) in reward for gallantry in saving life, and of the order of Victoria and Albert (1862).

BIBLIOGRAPHY.—By the Queen's authority, her secretary, General Grey, compiled *The Early Days of the Prince Consort*, published in 1867; and *The Life and Letters of the Prince Consort* (1st vol., 1874; 2nd, 1880) was similarly edited by Sir Theodore Martin. A volume of the *Principal Speeches and Addresses of Prince Albert*, with an introduction by Sir Arthur Helps, was published in 1862. *See* also C. F. von Stockmar, *Memoirs* (1872); the *Letters of Queen Victoria* (1907); and Lytton Strachey, *Queen Victoria* (1921). (H. C.)

**ALBERT** (1490–1568), last grand master of the Teutonic Order, and first duke of Prussia, was born at Ansbach, May 16, 1490, the third son of Frederick of Hohenzollern, prince of Ansbach and Bayreuth, and Sophia, daughter of Casimir IV., king of Poland. In 1511 Albert was made grand master of the Teutonic Order, which had held East Prussia under Polish suzerainty since 1466. In 1519 Albert was at war with his Polish suzerain, and though a truce was made in 1521 the dispute, which was referred to the emperor, remained unsettled. Albert was then converted to Protestantism, and, supported by the advice of Martin Luther, determined to make Prussia a hereditary duchy, though he was at the same time assuring Pope Adrian VI. that he intended to reform the Order and repress Lutheranism among the knights. Eventually in 1525 a treaty was signed at Cracow by Sigismund I. of Poland, agreeing to the creation of a duchy, provided it were held as a Polish fief, and Albert was formally invested on Feb. 10.

The new duke proceeded to further Protestantism in East Prussia. He was deposed from the grand mastership, but the Teutonic knights were unable to recover Prussia, and, although he was placed under the ban of the empire, it was never enforced. In imperial politics Albert was fairly active. Joining the league of Torgau in 1526, he acted in unison with the Protestants, and was among the princes who banded themselves together to overthrow Charles V. after the issue of the *Interim* in May 1548. The early years of Albert's rule in Prussia were fairly prosperous. Although he had some trouble with the peasantry, the lands and treasures of the church enabled him to propitiate the nobles and for a time to provide for the expenses of the court. He did something for the furtherance of learning by establishing schools in every town and by giving privileges to serfs who adopted a scholastic life. In 1544, in spite of some opposition, he founded a university at Königsberg, where he appointed his friend Osiander to a professorship in 1549. But Osiander's divergence from Luther's doctrine of justification by faith involved him in a violent quarrel with Melanchthon, who had adherents in Königsberg, and these theological disputes soon created an uproar in the town. The duke strenuously supported Osiander, and the area of the quarrel soon broadened. After Osiander's death in 1552, a preacher named John Funck, with an adventurer named Paul Scalich, exercised great influence over him. The state of turmoil caused by these religious and political disputes compelled the duke to consent to a condemnation of the teaching of Osiander, and in 1566 the estates appealed to Sigismund II., king of Poland, who sent a commission to Königsberg. Scalich saved his life by flight, but Funck was executed; the question of the regency was settled; and a strict form of Lutheranism was declared binding on all teachers and preachers. The duke, a disappointed man, lived for two years longer, and died at Tapiau on March 20, 1568.

Lohmeyer, *Herzog Albrecht von Preussen* (Danzig, 1890); E. Joachim, *Die Politik des letzten Hochmeisters in Preussen, Albrecht von Brandenburg* (Leipzig, 1892).

**ALBERT III.** (1443–1500), duke of Saxony, surnamed ANIMOSUS or THE COURAGEOUS, younger son of Frederick II., the Mild, elector and duke of Saxony, was born Jan. 27, 1443, and, after escaping from the hands of Kunz von Kaufungen, who had abducted him and his brother Ernest, passed some time at the court of the Emperor Frederick III. in Vienna. After the death of the Elector Frederick in 1464, Albert and Ernest ruled their lands together, but in 1485 a division was made by the Treaty of Leipzig, and Albert received Meissen, together with some adjoining districts, and founded the Albertine branch of the family of Wettin.

In 1475, Albert took a prominent part in the imperial campaign against Charles the Bold, duke of Burgundy, and in 1487 led an expedition against Matthias Corvinus, king of Hungary, which failed owing to lack of support on the part of the emperor. In 1488 he marched with the imperial forces to free the Roman king Maximilian from his imprisonment at Bruges, and after the king returned to Germany in 1489, Albert restored the authority of Maximilian in Holland, Flanders and Brabant. In 1498 Maximilian bestowed upon him the title of hereditary governor (potestat) of Friesland, but he had to make good his claim by force of arms. He was engaged in repressing a rising in Friesland when he died at Emden, Sept. 12, 1500. Albert, who was a man of great strength and considerable skill in feats of arms, delighted in tournaments and knightly exercises. His rule was a period of prosperity in Saxony in spite of the large sums which he spent campaigning in the emperor's service.

**ALBERT, DUKE OF WÜRTTEMBERG** (1865–1939), German general, the son of Duke Philip of Württemberg, was born in Vienna on Dec. 23, 1865. As the king and queen of Württemberg had no male heir, he was the heir presumptive to the Württemberg throne. He passed through the different grades of a military career and was appointed general in command of the XI. Army Corps at Cassel in 1906, and in 1908 was entrusted with the command of the Württemberg Army Corps. In 1913 he was advanced to the rank of generaloberst (colonel-general, immediately below field-marshal) and was appointed inspector-general of the VI. Army inspection. At the outbreak of World War I he took over the leadership of the IV. Army on the western front, was advanced to the rank of field-marshal-general in 1916 and appointed chief-in-command of the group of armies on the front in Alsace-Lorraine, which fought under his leadership until the end of the war. He married in 1893 the late Archduchess Margarete Sophie of Austria (d. 1902), the sister of the Archduke Francis Ferdinand, who was assassinated at Sarajevo. He died Oct. 29, 1939, at Stuttgart, Germany.

**ALBERT I.** (*c.* 1100–1170), margrave of Brandenburg, surnamed "the Bear," was the only son of Otto the Rich, count of Ballenstädt, and Eilika, daughter of Magnus Billung, duke of Saxony. He inherited the valuable Saxon estates of his father in 1123, and on his mother's death in 1142 succeeded to one-half of the lands of the Billungs. About 1123 he received from Lothair, duke of Saxony, the margraviate of Lusatia. In 1128 his brother-in-law, Henry II., margrave of the Saxon north mark, died, and Albert, disappointed at not receiving this fief, attacked Udo, the succeeding margrave, and was consequently deprived of Lusatia by Lothair. His services in Italy in 1132 were rewarded in 1134 by the investiture of the north mark, which was again without a ruler. For three years he was occupied in campaigns against the Wends, and by an arrangement made with Pribislaus, duke of Brandenburg, Albert secured this district when the duke died in 1150.

Taking the title margrave of Brandenburg, he pressed the warfare against the Wends, extended the area of his mark, did much for the spread of Christianity and civilization therein, and so became the founder of the margraviate of Brandenburg. In 1137 his cousin, Henry the Proud, had been deprived by King Conrad III. of his Saxon duchy, which was given to Albert. But he was driven from Saxony and also from his mark by Henry, and compelled to take refuge in South Germany, and when peace was made in 1142 he renounced the Saxon dukedom and received the counties of Weimar and Orlamünde.

It was possibly at this time that Albert was made arch-chamberlain of the empire, an office which afterwards gave the margraves of Brandenburg the rights of an elector. In 1162 Albert accompanied the Emperor Frederick I. to Italy, and distinguished himself at the storming of Milan. In 1164 he joined a league of princes formed against Henry the Lion, and peace being made in 1169, Albert divided his territories among his six sons. He died Nov. 13, 1170, and was buried at Ballenstädt. His personal qualities won for him the surname of "the Bear," and he is also called by later writers "the Handsome."

*See* L. von Heinemann, *Albrecht der Bär* (Darmstadt, 1864).

**ALBERT III.** (1414–86), elector of Brandenburg, surnamed ACHILLES because of his relentless energy and physical strength, and his combination of shrewdness and knight-errantry, was the third son of Frederick I. of Hohenzollern, elector of Brandenburg. Albert was born at Tangermünde on Nov. 9, 1414, and died at Frankfurt on March 11, 1486. On the division of territory which followed his father's death in 1440 he received the principality of Ansbach; on the death of his brother John in 1464 he inherited Bayreuth; and in 1470, on the abdication of his brother Frederick II., he became elector of Brandenburg. His main object was family aggrandizement, and he became as powerful among the northern as the elector of the Palatinate among the southern princes. He saw that division of inheritance weakened the family power, and he devised the famous *Dispositio Achillea* of 1473, which decreed that the mark of Brandenburg should descend intact to the eldest son, the younger son receiving the Franconian possessions of the Hohenzollerns. Both sections of the family lands were to descend thenceforward by primogeniture, a new principle in the succession of the German princely houses. He married his daughter Barbara to Henry VI. of Glogau, and after her husband's death secured a part of his Pomeranian lands for his daughter in 1482. The power of Brandenburg declined with his death. It is said that the old warrior, who had spent the greater part of his life either in fighting against the towns which desired to maintain their independence, or the princes who sought reforms, or in purely dynastic struggles, realized at the end of his life that military strength was useless so long as Germany had no sound peace, no good system of law and no general currency.

See *Das kaiserliche Buch des Markgrafen Albrecht Achilles, Vorkurfürstliche Periode, 1440–70,* ed. by C. Hoefler (Bayreuth, 1850); *Kurfürstliche Periode,* ed. by J. von Minutoli (1850); *Quellensammlung zur Geschichte des Hauses Hohenzollern,* Band I., ed. by C A. H. Burkhardt (Jena, 1857); O. Franklin, *Albrecht Achilles und die Nuremberger, 1449–53* (1866); *Politische Korrespondenz des Kurfürsten Albrecht Achilles, 1470–86,* ed. by F. Priebatsch (Leipzig, 1894–98); J. G. Droysen, *Geschichte der preussischen Politik* (1855–86).

**ALBERT** (1490–1545), elector and archbishop of Mainz, and archbishop of Magdeburg, was the younger son of John Cicero, elector of Brandenburg, and was born June 28, 1490, and died at Aschaffenburg Sept. 24, 1545. In 1513 he became archbishop of Magdeburg and administrator of the diocese of Halberstadt. In 1514 he obtained the electorate of Mainz, and in 1518 was made a cardinal.

Meanwhile to pay for the pallium of the see of Mainz and to discharge the other expenses of his elevation, Albert had borrowed a large sum of money from the Fuggers, and had obtained permission from Pope Leo X. to conduct the sale of indulgences in his diocese to obtain funds to repay this loan. For this work he procured the services of John Tetzel, and so indirectly exercised a potent influence on the course of the Reformation. When the imperial election of 1519 drew near, the elector's vote was eagerly solicited both by the partisans of Charles (afterwards the Emperor Charles V.) and of Francis I., king of France, and he appears to have received a large amount of money for the vote which he cast eventually for Charles. Albert's large and liberal ideas, his friendship with Ulrich von Hutten, and his political ambitions, appear to have raised hopes that he would be won over to the reformed faith; but after the peasants' war of 1525 he ranged himself definitely among the supporters of Catholicism. He was nevertheless compelled to grant religious liberty to the inhabitants of Magdeburg in return for 500,000 florins.

During his latter years indeed he showed more intolerance towards the Protestants. Albert adorned the *Stiftskirche* at Halle and the cathedral at Mainz in sumptuous fashion, and took as his motto the words *Domine, dilexi decorum domus tuae.* A generous patron of art and learning, he counted Erasmus among his friends.

May, *Der Kurfürst, Kardinal, und Erzbischof Albrecht II. von Mainz und Magdeburg* (Munich, 1865–75); W. Schum, *Kardinal Albrecht von Mainz und die Erfurten Kirchenreformation* (Halle, 1878); P. Redlich, *Kardinal Albrecht von Brandenburg, und das neue Stift zu Halle* (Mainz, 1900).

**ALBERT (FRIEDRICH RUDOLF ALBRECHT),** ARCHDUKE (1817–1895), Austrian field-marshal, the eldest son of the Archduke Charles (Karl Friedrich), was born Aug. 3, 1817, in Vienna. After having been educated under the careful superintendence of his father, he entered the Austrian army as a colonel of infantry in 1837, and was transferred to the cavalry arm in 1839, and became a lieutenant-field-marshal in 1843. He learned the art of war from Radetzky. At this time the Austrian generals and staff officers had committed themselves blindly to the strategical method of the Archduke Charles, the tradition of whose practical soldiership survived only in Radetzky and a few others. Albert chose to follow Radetzky, and was thus saved from the

pseudo-scientific pedantry which brought defeat to the Austrian arms in 1859 and in 1866.

He fought under Radetzky as a volunteer throughout the campaign of 1848, having been present at the action of Pastrengo and the battles of Santa Lucia and Custozza. In the following campaign he applied for and obtained the command of a division in the 2nd corps (under d'Aspre), though his previous grade had been that of commander-in-chief. The splendid fighting of the corps at Novara was decisive, and Radetzky named d'Aspre, Count Thurn, and the archduke as the general officers worthy of the greatest rewards. In 1850 he became a general of cavalry, and in 1851 military and civil governor of Hungary, a position which he retained until 1860, when he was relieved at his own request.

Soon afterwards he was appointed to succeed Radetzky as commander-in-chief in Italy, and in 1863 he was promoted to the rank of field-marshal. When war became imminent in 1866, the archduke took command of the field army in Italy. For the story of the campaign of 1866 in Italy, *see* ITALIAN WARS. The operations of the archduke, who disposed of considerably inferior forces, were crowned with success in the brilliant victory of Custozza (June 23), and his reputation as a general-in-chief was firmly established during only eight days of field operations, though it is possible that his chief of staff, Lieutenant-Field-marshal von John, contributed not a little to the success of the Austrian arms.

The result of Custozza was the retreat and complete immobilization of the whole Italian army, so that Albert was able to dispatch the greater part of his troops to reinforce the Bohemian army, when, after having been defeated by the Prussians, it fell back on Vienna. On July 10 the archduke was summoned to Vienna to take supreme command of the forces which were being collected to defend the capital, but peace was made before further hostilities took place. From this time, under various titles, he acted as inspector-general of the army.

Like his father, and with better fortune, he was called upon to reorganize the military system of his country on an entirely new plan, learned, as before, by defeat. The principle of universal short service, and the theory of the armed nation, were necessarily the groundwork of the reforms, and the consequent preparation of all the national resources for their task in war, by the superintendence of peace administration, by the skilful conduct of manoeuvres, was thenceforward the task of his lifetime. In 1870 he conducted the military negotiations preparatory to an alliance with France, which, however, was not concluded. He retained personal control of the army until his last illness, which he contracted at the funeral of his nephew Francis, ex-king of Naples. His only remaining brother, the Archduke Wilhelm, had died a few months before, as the result of an accident. He himself died Feb. 18, 1895. His only son died in childhood, and his nephew Archduke Frederick (born 1856) inherited his great possessions, including the Albertina, a famous collection of books, manuscripts, engravings and maps, founded by Duke Albert of Saxe-Teschen.

Among the military works of the Archduke Albert, *Über die Verantwortlichkeit im Kriege* created a sensation, and was translated into English and French. He also wrote *Gedanken über dem Militärgeist; Über die höhere Leitung im Kriege;* and *Kritische Betrachtungen über den Feldzug 1866 in Italien.* He was the principal editor of the military works of his father.

*See* Mathes v. Bilabrueck, "Gedenkrede auf Weiland Sr. K. u. K. H. Erzh. Albrecht," *Mil.-Wissenschaftl. Verein* (1895); Teuber, *F. M. Erzh. Albrecht, ein Lebensbild* (Vienna, 1895); Duncker, *F. M. Erzherzog Albrecht* (Vienna and Prague, 1897).

**ALBERT,** also named ALEXANDRE MARTIN (1815–1895), the first industrial working-man to enter a government, was a member of the French Provisional Republican Government in Feb. 1848. He signed all decrees "ALBERT, *ouvrier,*" and followed implicitly the guidance of Louis Blanc (*q.v.*). He was sentenced to ten years' deportation on political grounds in 1849. On his release he secured employment as a gasworker.

**ALBERT,** MADAME (*c.* 1805–1846), French actress, whose maiden name was Thérèse Vernet, was born of a family of players. Her grace, beauty, and distinction of manner made her the idol of Paris, and her circle of admirers was widened by long tours of the provinces and abroad.

**ALBERT (OF AIX)** (fl. *c.* A.D. 1100), historian of the first crusade, was canon and *custos* of the church of Aix-la-Chapelle He wrote a *Historia Hierosolymitanae expeditionis* or *Chronicon Hierosolymitanum de bello sacro,* a work in 12 books, between 1125 and 1150. This book gives the history of the first crusade and of the Latin Kingdom of Jerusalem down to 1121. It was well known during the middle ages, and was largely used by William, archbishop of Tyre, for the first six books of his *Belli sacri historia.* The first edition of the history was published at Helmstadt in 1584, and a good edition is in the *Recueil des historiens des croisades,* tome iv. (Paris, 1841–87).

Krebs, *Zur Kritik Alberts von Aachen* (Muenster, 1881); H. von Sybel, *Geschichte des ersten Kreuzzuges* (Leipzig, 1881); B. Kugler, *Albert von Aachen* (Stuttgart, 1885); F. Vercruysse, *Essai critique sur la chronique d'Albert d'Aix* (Liége, 1889).

**ALBERT, LAKE (A. NYANZA),** Uganda, situated in 1° 9′ to 2° 17′ S., and 30° 30′ to 31° 35′ E. Its greatest length is 100 mi., its greatest breadth 22 mi., and its greatest depth 55 ft. The area is approximately 1,640 sq.mi.; *i.e.,* about the size of Lancashire. The height of the lake surface above sea level is given as 2,037 ft., but this is liable to seasonal and other fluctuations.

The lake lies on the floor of the western branch of the Rift valley. Thermal springs occur at Kibiro, and again between the Murchison falls, on the Victoria Nile, and Wadelai. At Kibiro salt springs are exposed on the strand in the dry season, and give rise to a native trade in salt. At the southern end of Albert Nyanza is a wide plain, traversed by the Semliki river, which enters the lake through a swamp of tall weeds, chiefly ambach and papyrus. On both the eastern and western sides the walls of the Rift valley are close to the lake, the water in many cases washing the base of the cliffs. Elsewhere the narrow foreshore is thickly wooded. The ascent to the plateaux is generally by a series of abrupt steps. On the western side the mountains present many pointed and conical summits, some of which may be nearly 8,000 ft. above the lake; on the eastern side the cliffs rise sharply for 1,000 to 2,000 ft. On either coast wild ravines, densely wooded, break the outline of the mountains. Through these gorges and over the plateau-edge fall magnificent cascades. Towards the north the hills recede from the coast and on both sides flats extend for distances varying from ·5 mi. to 15 mi. On the eastern side, 92 mi. from the southern end of the Nyanza, the Victoria Nile enters the lake, here not more than 6 mi. across, through a wilderness of woods, the delta of the Nile extending over 4 mi. The mouth of the main stream is obstructed by a bar of its own formation; the current is sluggish; there are many side channels, and the appearance of the lake gives no hint that a great river has joined its waters. For 5 mi. or 6 mi. north of the junction of the Victoria Nile the lake suffers no material diminution in width. Then, however, the eastern and western shores approach each other, and a current is perceptible flowing north. The lake has become the Bahr-el-Jebel, or Mountain river, as this section of the Nile is called. Albert Nyanza is shallow; at its southern end the water for a considerable distance is not more than 3 ft. deep. The deepest soundings give only 50 ft. to 55 ft., the average depth being 30 to 40 ft.

**The Albertine Basin of the Nile.**—Albert Nyanza receives the whole of the drainage of Edward Nyanza and the Semliki river, and with them forms the "Albertine" Nile system. Its waters, as stated above, mingle with those of the Victoria Nile. There is evidence of very considerable shrinkage in the size of these lakes. Within human times the level of Albert Nyanza appears to have been 1,000 ft. higher than it is at present. The causes of this fall have not been fully explained. Both tectonic and climatic agencies may be involved. River erosion is probably also a complicating factor. In recent geological times the valley to the north of Edward Nyanza, then much larger than now, was blocked. The removal of the block led to the shrinkage of the lake and the formation of the Semliki, which found its way to the more northern lake—Albert Nyanza. Gradually the Semliki eroded its bed, and consequently the level of Edward Nyanza

continued to fall. The process continues but is checked by the existence of the rock barrier which stretches across the Semliki. This stream leaves Edward Nyanza at its northwest end in 0° 8′ 30″ S., and after a course of about 160 mi. enters Albert Nyanza in 1° 9′ N. In its upper and in its lower course the river flows either through high alluvial plains, in which it has scored a deep channel, or across swamp land. In the middle section, which has a length of some 75 mi., the river runs in a deep narrow valley covered with the densest forest. On the west this valley is bounded by the Congo mountains, which form the wall of the Rift valley, on the east by the mighty range of Ruwenzori, whose heights tower over 16,000 ft. above sea level. In this length of 75 mi. the river falls in cataracts and rapids over 800 ft.

Albert Nyanza, on the other hand, is threatened in the distant future with destruction from another cause—the filling of its bed by the alluvium poured into it by the Semliki, the Victoria Nile and other streams. The Semliki receives directly or indirectly the whole of the drainage of Ruwenzori, and also that of the eastern face of the Congo mountains as well as the drainage basin of Edward Nyanza. The Semliki, as it emerges from the region of forest and cataracts and deposits much of its burden, becomes sluggish as its slope flattens out. This process has formed a large plain at the south end of Albert Nyanza, which has seriously encroached upon the lake. At the northern end of the lake the sediment brought down by the Victoria Nile is producing a similar effect. Nyamsasi, which was an island at the southwest end in 1889, has become a peninsula. Islands which in 1876 were on the east coast no longer exist; they now form part of the foreshore. On the other hand, the shrinkage of the lake level caused the appearance in 1885 of an island where in 1879 there had been an expanse of shallow water. It seems probable that, in a period geologically not very remote, the "Albertine" system will consist of one great river, extending from the northern slopes of the Kivu range, where the Ruchuru has its rise, to the existing junction of the Victoria Nile with Albert Nyanza.

The combined drainage area, including the water surface of Edward Nyanza, the Semliki and Albert Nyanza, is some 16,600 sq.mi. Throughout this area the rainfall is heavy (40 in. to 60 in. or more per annum), the volume of the Semliki in flood being not less than 700 cu.mi. per second. Of the water received by Albert Nyanza annually (omitting the Victoria Nile from the calculation) between 50% and 60% is lost by evaporation, while 24,265,000,000 cu.mi. are annually withdrawn by the Bahr-el-Jebel. The "Albertine" system plays a comparatively insignificant part in the annual flood rise of the White Nile, but to its waters are due the maintenance of a constant supply to this river throughout the year.

**Discovery and Exploration.**—Albert Nyanza was first reached by Samuel Baker on March 14, 1864, near Vacovia, a small village of fishermen and salt-makers on the east coast. Albert Nyanza was entered on his map as a vast lake extending about 380 mi. But the circumnavigation of the lake by Gessi Pasha (1876) and by Emin Pasha in 1884 showed that Baker had been deceived as to the size of the lake. The lake forms part of the (British) Uganda Protectorate, but the northwest shores were leased in 1894 to the Congo Free State. Of this leased area a strip 15 mi. wide, giving the Congo state a passageway to the lake, was to remain in its possession after the determination of the lease. (*See* also NILE.)

**ALBERTA,** province of Canada, created 1905. Area 255,285 sq.mi. (land 248,800, water 6,485). The population in 1951 was 939,501.

**Geography and Geology.**—Alberta has a natural geographical boundary only on its western side, the watershed of the Rocky mountains. On the north the parallel of 60° N. separates it from the Northwest Territories, on the east the meridian of 110° W. from Saskatchewan and on the south the parallel of 49° N. from the United States. Geographically it is thus divided as between the wooded mountain slope from the hills, and the drainage basins of three river systems below. A small southern part of the province is drained by the Milk river, a tributary of the Missouri. Of the rest of the province the lower half, mainly prairie land, the more thickly settled portion, is drained by the waters and branches of the South and North Saskatchewan. The northern, less settled portion, a more rolling country of woods and grassland, is drained by the Athabasca and the Peace.

Geologically the greater part of Alberta belongs to the interior continental plain showing in the southwest a general elevation of about 3,500 ft. and in the extreme northeast at the Great Slave river only 600 ft. The mountainside strip of the eastern slope of the Rockies is a part of the Cordilleran belt; the summits of the Rockies bordering Alberta show an altitude of 8,000 to 9,000 ft. with many peaks over 10,000, while the passes used by the railways show 4,450 ft. for the Crowsnest Pass station, 5,332 for Kicking Horse (C.P.R. main line) and 3,711 for Yellowhead Pass station (C.N.R.).

**Climate.**—Sir Frederic Stupart, director of the Meteorological Service of Canada (1894–1929) said that "it is doubtful whether any other territory on the face of the globe has a climate as variable in the winter as that of Alberta." The normal winter is cold, extreme cold persisting in some years from November to March, inclusive, but in others the Chinook winds, the warm winds from the west carried over the Rockies, dominate the winter. April shows an average temperature of 53° at Calgary, 53° at Edmonton, 58° at Medicine Hat. The average July–August temperatures are 75° at Calgary, 74° at Edmonton, 82° at Medicine Hat, with a usual summer limit of 90° and records of over 100°. The isothermal lines run from the Rockies to the United States border in a southeastern direction. The January mean temperature of 0° passes a little north of Edmonton and crosses lower Saskatchewan to North Dakota. The line of −15° slants across northern Alberta passing Fort Vermilion on the Peace river and circling the lower Hudson bay to Ungava. The four winter months, December to March, show averages: Calgary 18°, Edmonton 14°, Dunvegan 6° and Chipewyan −3°. The summer isotherms are complicated and diverge greatly from an east to west direction to form loops. Most of the province shows July isotherms of 60° to 65°. The Peace river country round Dunvegan and the Lake Athabasca district have much the same summer heat as Calgary with longer sunlight, favouring growth. The average rainfall till the end of July is nearly equal to that of Ontario except in the drier southern belt. A change of wind from a northeast blow to a southwestern Chinook at times changes the temperature from 20° below to 40° above zero in a few hours.

**History.**—Alberta was originally a part of the Hudson's Bay territory granted by the charter of 1670. It remained long unknown. Following the lead given by Pierre de la Vérendrye, Pierre Boucher, sieur de Boucherville, made his way across the plains and set a temporary stockade, Fort Jonquière, at the foot of the Rockies in 1751. But even in 1774 the Hudson's Bay company had no post west of Cumberland House, established that year on the lower Saskatchewan. The North West company, formed in 1783, disregarding the Hudson's Bay company charter, first penetrated that empty region. Under their auspices Alexander Mackenzie in 1789 descended the Athabasca and the Mackenzie to the sea and in 1792–93 ascended the Peace river and crossed the Rockies to the Pacific. Mackenzie founded Fort Chipewyan (Lake Athabasca) in 1789. Both companies founded posts near Edmonton (1795) but the fur trade developed northward.

The transfer of the northwest in 1869 from the Hudson's Bay company to the new dominion led to surveys for railroads (Sir Sandford Fleming, 1871) and to the Homestead act for settlement (1875), the establishment of the Northwest mounted police (1873) and, on completion of the Canadian Pacific railway (1885), to a continued influx of settlement from older Canada, from overseas and across the border which assumed the proportions of an invasion after 1900. Migration from continental Europe was a special feature. Settlement led to territorial government at first under the Northwest Territories act of 1875. An act of 1882 separated out four provincial "districts" (Assiniboia, Saskatchewan, Alberta, Athabasca) leaving west of Hudson bay the area north of 60° as Northwest Territories (*see* NORTHWEST TERRITORIES). Later in the same year Regina was established as the seat of government. There first appeared on the map the name Alberta (lower half of the present) as a tribute to Queen Victoria, recalling the memory of the prince consort through his daughter Princess Louise Alberta. At the census of 1901 Alberta and Athabasca (the area now Alberta) had a population of 73,022; Calgary, of 4,392; and Edmonton, of 4,176. The ensuing rapid settlement led in 1905 to the creation of the present province of Alberta, beside the sister province of Saskatchewan. The provinces had at once the status conferred by the British North America Act of 1867 but, to facilitate settlement, the public domain remained under federal control until 1929, when it was transferred to the provinces. Good times brought rapid growth, with the organization of education (University of Alberta at Edmonton, 1907), the professions and cultural life but with grain farming as the economic basis. The population reached 374,295 in 1911 and 588,454 in 1921. The service of Alberta in World War I belongs in general Canadian history.

The ministerial government of the new province was at first oper-

ated by parties formed on the standing model of conservatives and liberals. But the special agrarian interests of the province led to the creation of a United Farmers' association, which presently entered the political sphere and gained control of the government in 1921. The United Farmers' policy was chiefly connected with co-operative marketing of grain which gained great ascendancy and prestige by the temporary success of provincial "pools" united by a central marketing board for the prairie provinces. Depression and the collapse of prices proved too great a burden for the pools, which gave place to government regulations of wheat prices. The result led to the defeat of the farmers' parties by the Social Credit party, led by William Aberhart, which gained office in 1935 and undertook to pass legislation for forced conversion of the public debt, or cancellation, whole or partial, of existing land mortgages, the issue of provincial paper money in the form of legal tender certificates and the restriction of the press. All these measures underwent judicial revision and abrogation by both local and federal disallowance, and by the decisions of the supreme court of Canada and then of the privy council. For details of this complicated record *see* the special *Rowell-Sirois Report of 1940* and the *Case for Alberta* as presented by the province under that name to the above commission.

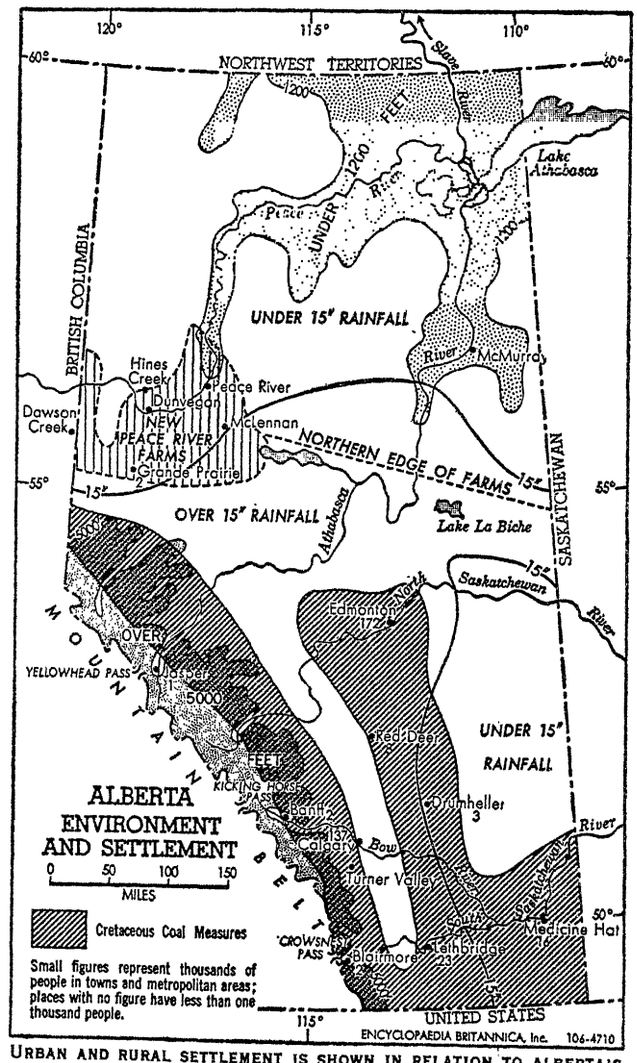
**Resources.**—The natural resources of Alberta are on a colossal scale. Of its total land area of 248,800 sq.mi., 136,640 was classed (1946) as agricultural land present or potential, of which 48,295 was forested land fit to be cleared for agriculture. Of a total of 130,620 sq.mi. of forest land, 37,560 is nonproductive land, but it serves to shelter game and conserve rainfall. The geological survey of Canada estimates the coal area of the province at 16,588 sq.mi. containing a possible reserve of 47,874,300,000 tons. Petroleum from the subterranean oil pools of the Turner valley, Leduc, Redwater, Woodbend and other foothill areas constitutes 97% of the Canadian output. Geological investigation points to the existence of similar pools in the Peace River district. Natural gas is found abundantly in different localities while the tar sands of the Athabasca offer a major potential source of oil not yet put to commercial use. In point of water power Alberta at mid-20th century showed available 24-hr. horsepower (at ordinary six months' flow) of 1,258,000; actual turbine installation (Dec. 1949) was 107,225 h.p. This compares with a Canadian total available of 42,899,000 h.p. and installed 11,613,333 h.p. The fisheries of Alberta include whitefish, pickerel, trout, etc., from its lakes and rivers.

**Population.**—The population of Alberta, census of 1951, was 939,501; Calgary, 129,060; Edmonton, 159,639. In national and cultural origin because of migration as described above it is more varied than the people of any other Canadian province. The Canadian census classification did not show Americans (of the U.S.) as a racial class but distributed them by origin. Taken thus (1941 census) the population of Alberta was 53% British, 10% German, 7.5% Ukrainian, 5% French, 3.6% Norwegian, 2.8% Polish, 1.7% Dutch, 1.6% Italian and the rest various with 2% native Indian.

**Finance.**—The province of Alberta had at its inception a public revenue of $1,425,059, which had grown by 1947 to $54,626,000. The gross public bonded debt, nil in 1905, reached $29,000,200 in 1916 and $139,350,000 by 1947. The chief sources of revenue are federal subsidies, gasoline taxes, succession duties, corporation taxes and revenue from liquor control and petroleum leases.

**Agriculture.**—In the economy of Alberta agriculture naturally fills the largest place. Its relative place may be gauged from the following data, collected in 1948: total gross value of production in Canada $18,143,186,852; in Alberta $1,073,361,412 (compare Ontario leading with $7,672,980,044); total net value of agriculture production in Canada $1,994,391,000; in Alberta $388,420,000 (compare Ontario leading with $496,334,000). In 1948 agriculture accounted for 58% of the net output of the province as compared with 16% for manufactures, 12% for mining and 9% for construction.

Agriculture in Alberta was greatly aided by irrigation of the drier areas. Surface waters were vested in the crown and the Irrigation Districts acts of Alberta provided for forming districts, initiating projects and raising loans by local votes. The chief sources of water are the Bow, the St. Mary, the Milk and the Oldman rivers. The total irrigable area of the 15 major projects as reported in 1948 was 719,035 ac. and in addition there were about 700 private irrigation systems covering 70,000 irrigable acres.



**Crops.**—In Alberta the 1949 area planted in spring wheat was 7,586,000 ac. (average, 1943–47, 6,402,000 ac.), as compared with oats, 2,255,000 ac. (average, 1943–47, 3,098,000 ac.), and barley, 2,118,000 ac. (average, 1943–47, 2,073,000 ac.). Rye (planted both spring and fall) is a lesser crop—in 1949, 325,000 ac. (average, 1943–47, 181,000 ac.). Sugar beets expanded from 14,000 ac. in 1935 to 32,000 in 1949. Statistics show for Alberta, for 1949, field crops $338,778,000 (compare 1940, $136,572,000); farm animals $205,733,000 (1948) (compare 1940, $47,801,000); milk $43,102,000; poultry and eggs $22,845,000; fur farming $3,761,727; clover and grass seed $10,241,000.

**Environment and Settlement.**—In order to understand the possibilities of settlement in Alberta, the general environment must be studied closely; the necessary data are charted in the accompanying map. The mountain belt of Alberta (more than 5,000 ft.) is confined to the extreme southwestern margin along the Rocky Mountain uplift. There are many complicated formations, mainly of Cambrian age. But on the eastern edge the much younger Cretaceous formations are also involved in the folding. Consequently there are valuable coal seams, especially in the vicinity of Kicking Horse pass and Crowsnest pass, right in the mountain area.

Throughout the south of Alberta the formations are fairly level-bedded, and are almost all of Cretaceous age. Coal seams are found at three levels in these Cretaceous rocks; and for a time they were thought to contain almost the largest resources of coal in the world. Later estimates gave them about 47,874,300,000 tons, about equal to the resources of the Bohemian or Donetz coal fields in eastern Europe. Red Deer, Drumheller and Lethbridge contain the chiel coal mines worked in these fairly level coal seams. (The coal measures are indicated in the map.) Just below the lowest coal seams a layer of porous rocks at Turner Valley contains petroleum, about 3,000 ft. below the surface. In 1947 a new major field was discovered at Leduc, 18 mi. S. of Edmonton, and there are other fields of almost equal importance in production in other parts of Alberta.

Despite these important petroleum resources, it is because of agriculture that Alberta shows greatest promise. The rainfall conditions are satisfactory in most of the province, excluding the southeast corner. The rain lines for 15 in. are shown in the map and form a sort of wet belt across the province about the latitude of Edmonton. The rain falls off to 11 in. in the extreme northeast, and also near Medicine Hat. The cooler climate of the north of the province gives the rainfall more value than in the far southeast, where ranching replaces farming to some extent. The main areas occupied in the Peace River settlements are shown, and by 1941 there were almost 50,000 settlers there. In 1911 there had only been 1,100 people in the district. Grand Prairie, Peace River and McLennan are three of the small towns. To the northeast of Edmonton the notable population extends only to Lake La Biche; the edge of settlement is shown on the map.

Thus, of the 940,000 people living in Alberta, almost the whole number lie south of the line joining Lake La Biche to Dunvegan, while in the rather arid portion north of Medicine Hat the population is

URBAN AND RURAL SETTLEMENT IS SHOWN IN RELATION TO ALBERTA'S CLIMATIC AND PHYSIOGRAPHIC ENVIRONMENT AND TO THE PRINCIPAL NATURAL RESOURCE OF THE PROVINCE—COAL

also very sparse. If reference is made to the temperature maps of Canada, it will be found that the July isotherm of 57° F.—which determines the climatic limits of crops—runs far to the north of any part of Alberta. Hence, it may be expected that a hay-potato-oats type of farming would in the distant future expand over a good deal of the empty country of north Alberta. However, since Alberta has much greater coal resources than the other provinces, and since the oil resources invite subsidiary chemical plants, it seems likely that there might also be increasing development of industrial settlement.

**Government Aid.**—Extensive and detailed assistance to the farming community is given by the provincial department of agriculture through field crop, livestock, dairy, poultry, veterinary services, agriculture branches. Expert agriculturists located in 43 different districts conduct short courses, field days and lecture demonstrations. Publications on agriculture and home economics are distributed free. Students attend each year the schools of agriculture at Olds and Vermilion, each school having a demonstration. A provincial horticultural station is maintained at Brooks.

**Manufactures.**—As in all the prairie provinces manufactures in Alberta occupy a secondary place and are confined to secondary forms of manufacture rather than the heavy industries. Of particular importance are the 69 flour mills of the province, and the meat-packing plants of Edmonton. Other manufactures in Edmonton are those of furniture, general lumber, biscuits and clothing, and oil refining. The manufactures of Calgary include meat packing, woodworking, oil refining and a nitrogen plant. The total (1947) value of manufactures in the province was (gross) $296,054,129. At the latest complete classification (1947) Calgary was reported as having 246 establishments with 7,790 employees; Edmonton 222 with 7,625; Medicine Hat 27 with 1,049; and Lethbridge 37 with 893.

**Transport and Communications.**—The southern half of Alberta is well supplied with railways now extending northward to connect with steam navigation down the Mackenzie river system. The total mileage in 1949 apart from second tracks and sidings was 5,643. The Canadian Pacific railway, the first road constructed across the province, created the town of Calgary as a proper junction point for a line on the North Saskatchewan at Fort Edmonton. The Grand Trunk Pacific (later Canadian National), initiated in 1903 and completed in 1915, was built across the more fertile valley of the South Saskatchewan to pass through the Yellowhead pass and so to Vancouver by the valley of the Fraser with a northern branch to reach the Pacific 500 mi. farther north at the mouth of the Skeena river (Prince Rupert) There is a third railway route, the most southerly and the shortest, through the Rockies via the Crowsnest pass by the Canadian Pacific railway. From both of the present railway systems branch lines reach various points in the southern province. Northern connections from Edmonton are made by the Canadian Pacific to the Athabasca river waterways (Fort McMurray) and across the Peace River valley (C.P.R.) to Hines Creek and to Dawson Creek (B.C.), just beyond the provincial boundary. This point became the railhead for the Alaska highway, military and international, connecting with rail at Fairbanks, Alaska. The Banff-Jasper highway, completed in 1940, connects Banff, Lake Louise and Jasper.

**ALBERT EDWARD NYANZA:** *see* EDWARD, LAKE.

**ALBERTI, DOMENICO** (*c.* 1710–1740), Italian musician, achieved unawares something like immortality in musical history as the writer of dozens of sonatas in which the melody is supported from beginning to end by an extremely familiar, but nowadays little-esteemed, formula of arpeggio accompaniment, consequently known as the Alberti bass.

**ALBERTI, LEONE BATTISTA** (1404–1472), Italian painter, poet, philosopher, musician and architect, was born in Venice on Feb. 18, 1404. He was so skilled in Latin verse that a comedy he wrote in his 20th year, entitled *Philodoxius,* deceived the younger Aldus, who edited and published it as the genuine work of Lepidus. In music he was reputed one of the first organists of the age. At Rome he was employed by Pope Nicholas V in the restoration of the papal palace, and of the foundation of Acqua Vergine, and in the ornamentation of the magnificent fountain of Trevi. At Mantua he designed the church of Sant' Andrea, at Rimini the church of San Francesco, which is generally esteemed his finest work, and in Florence the principal façade of the church of Santa Maria Novella, as well as the family palace now known as the Palazzo Strozzi. His most celebrated treatise is that on architecture, *De Re Aedificatoria,* which was translated into Italian, French, Spanish and English.

*See* Passerini, *Gli Alberti di Firenze* (1869–70); Mancini, *Vita di Alberti* (Firenze, 1882); V. Hoffmann, *Studien zu Leon Battista Alberti's zehn Büchern: De Re Aedificatoria* (Frankenberg, 1883).

**ALBERTINELLI, MARIOTTO** (1474–1515), Italian painter, was born in Florence, and was a fellow pupil and partner of Fra Bartolommeo, with whom he painted many works. His chief paintings are in Florence, notably his masterpiece, the "Visitation of the Virgin" (1503) at the Uffizi.

**ALBERTITE,** a pyrobitumen (*see* BITUMEN) so named from the type occurrence in Albert county, New Brunswick. It is jet black in colour, has a brilliant lustre and a conchoidal to hackly fracture. It occurs typically in veins up to many feet in thickness and is a derivative of petroleum. (J. R.)

**ALBERT LEA,** a city of Minnesota, U.S.; the county seat of Freeborn county; the population, predominantly Scandinavian, was 13,488 in 1950 and 12,200 in 1940 by the federal census. It is on federal highways 65, 69 and 16, and is served by the Rock Island, the Chicago, Milwaukee, St. Paul and Pacific, the Illinois Central and the Minneapolis and St. Louis railways. The city is between Lake Albert Lea and Fountain lake in the south central part of Minnesota.

Diversified manufactures include food and beverage products, building equipment, tools and machinery, castings, wood products, fertilizer, concrete products, paint, plastic, clothing, athletic equipment, prefabricated buildings, shaving cream and numerous others.

The city takes its name from Col. Albert Miller Lea (1808–91), a West Point graduate (1831) who visited the area in 1835 as topographer with the U.S. dragoons. Colonel Lea wrote extensively of the area and is credited with naming the state of Iowa. A post office was established at Albert Lea in 1855, and the city received its charter in 1878. The city has a council-manager form of government.

**ALBERT MEDAL,** a British decoration instituted in 1866 as an award for signal acts of bravery in saving life at sea, and extended in 1877 to acts of bravery on land. The conditions governing the award were amended in 1905. There are two classes, each with two divisions. The medal, which is in gold for the 1st class and bronze for the 2nd, is oval, and bears the monogram V.A. The ribbon is either blue (for bravery at sea) or crimson (for bravery ashore) with white vertical stripes.

**ALBERTUS MAGNUS,** ALBERT OF COLOGNE (1206?–1280), scholastic philosopher called *doctor universalis.* Albert was born of the family of the counts of Bollstädt, at Lauingen, in Suabia. In 1223 he joined the Dominican order, and after teaching in turn at Cologne, Hildesheim, Freiburg, Ratisbon, Strasbourg and again at Cologne, was sent to Paris from 1245 to 1248, and there acquired great fame. (Roger Bacon, who was by no means friendly toward Albert, speaks of him as "the most noted of Christian scholars.") When he returned to Cologne in 1248 to organize the *studium generale,* Thomas Aquinas, who had been under his direction at Paris, went with him. From 1254 to 1257 he was provincial of the German province, during which time he defended the Mendicants against the University of Paris and its spokesman, William of St. Amour. From 1260 to 1262 he held the bishopric of Ratisbon. From that date to 1270, when he returned to Cologne as a *lector,* he seems to have been travelling about preaching a crusade in Germany and Bohemia, and undertaking various other ecclesiastical missions in Würzburg and Strasbourg. In 1277 he returned to Paris to defend the doctrines of Aquinas against the condemnations of Bishop Tempier. Albert's works, which were mostly completed before 1256, were published in 21 folio vol. by Jammy at Lyons in 1651, and reprinted in 36 vol. by Borguet (Paris, 1890). They include paraphrases of all of Aristotle's works, a commentary on the *Sentences* of Peter Lombard, an incomplete *Summa Theologiae,* a treatise against Averroes and the curious *De Causis et Processu Universitatis*—a work of Neoplatonic colouring.

Albert has a remarkable affinity with the early Franciscan philosophers of Oxford; thus, his love of experimental science, and his knowledge of geography, astronomy, medicine, zoology and botany, are strongly reminiscent of Robert Grosseteste and Bacon, while his interweaving of Aristotelian, Arabian, Jewish, Neoplatonic and Augustinian elements bears a close resemblance to the system of Thomas of York. However, as far as his Dominican successors are concerned, Albert's chief influence seems to lie in his successful propagation of an esteem for Aristotle. Hence, his project of "adapting Aristotle to the use of the Latin races" was fulfilled in spite of the intense distrust of Aristotle that had been

aroused by the Paris condemnations of his works on natural science and metaphysics in 1210, 1215, 1231 and 1245.

Gaul, *Alberts des Grossen Verhältnis zu Plato* (1913); G. von Hertling, *Albertus Magnus, Beiträge zu seiner Würdigung* (1914).

**ALBERUS, ERASMUS** (*c.* 1500–1553), German humanist and poet, was born at Sprendlingen, near Frankfort, and died at Neubrandenburg on May 5, 1553. He was almost the only member of Luther's party who commanded an effective weapon of satire. He ridiculed the Franciscan order in his *Barfüsser Mönche Eulenspiegel und Alkoran* (1542, preface by Luther), and gave his views on church and state in a collection of fables entitled *Buch von der Tugend und Weisheit* (1550). Some of his hymns are used in the Lutheran hymnal.

BIBLIOGRAPHY.—*Das Buch von der Tugend und Weisheit* has been edited by W. Braune (1892); the 16 *Geistliche Lieder* by C. W. Stromberger (1857). Alberus's prose writings have not been reprinted in recent times. *See* F. Schnorr von Carolsfeld, *Erasmus Alberus* (1894).

**ALBI,** a city of south-west France, in the department of Tarn, 48m. N.E. of Toulouse, on a branch line of the Southern railway. Pop. (1946) 34,342. It occupies a commanding position on the left bank of the Tarn, where its valley broadens as it emerges from the high *Plateau Central* toward the plain of Toulouse; a bridge crosses to La Madeleine (a suburb).

Albi (*Albiga*) was capital of the Gallo-Roman Albigenses, and later of the viscounty of Albigeois, a fief of the counts of Toulouse. From the 12th century onward its bishops encroached on the authority of the viscounts and, after the Albigensian War, lost their estates, which passed ultimately to the Crown. By a convention (1264), the chief temporal power was granted to the bishops. A nucleus of narrow, winding streets is surrounded by boulevards, beyond which lie modern quarters. The cathedral of Sainte Cécile, a fine Gothic fortress-church built in 1277–1512, is without transepts or aisles; the rood-screen and the choir-enclosures (about 1500) are masterpieces. The 14th-century archbishop's palace to the northeast is fortified.

The church of St. Salvi belongs to the 13th and 15th centuries. There are dye-works, cement-works, coal-mines, glass-works and important flour-mills. Hats, cloth fabrics, umbrellas, artificial silk and agricultural implements are also made. Trade is in wheat, wine, and prunes. Albi is the seat of an archbishop (1678), a prefect, and a court of assizes. It has tribunals of first instance and of commerce, a board of trade arbitrators and a chamber of commerce.

**ALBIA,** a city of Iowa, U.S., 68 mi. S.E. of Des Moines, in a fertile farming and stock-raising district and in the Albia coal field; the county seat of Monroe county. It is a junction point of the Burlington, the Wabash, and the Minneapolis and St. Louis railways, and is the northern terminus of the Iowa Southern Utilities company. It has several industrial plants, and is an important distributing centre for the coal and agricultural products of the region. The population in 1950 was 4,823; in 1940, 5,157.

**ALBIGENSES,** the usual designation of the heretics—and more especially the Catharist heretics—of the south of France in the 12th and 13th centuries. This name appears to have been given to them at the end of the 12th century, but the designation is hardly exact, for the centre of the movement was at Toulouse and in the neighbouring districts rather than at Albi (the ancient *Albiga*). The heresy, which had penetrated into these regions probably by trade routes, came originally from eastern Europe. The name of Bulgarians (*Bougres*) was often applied to the Albigenses, and they always kept up intercourse with the Bogomil sectaries of Thrace. Their dualist doctrines, as described by controversialists, present numerous resemblances to those of the Bogomils (*q.v.*), and still more to those of the Paulicians, with whom they are sometimes connected. It is exceedingly difficult, however, to form any very precise idea of the Albigensian doctrines, as our knowledge of them is derived from their opponents, and the very rare texts which have come down to us, emanating from the Albigenses (*e.g.*, the *Rituel cathare de Lyon,* ed. by Cunitz, Jena, 1852, and the *Nouveau Testament en provençal,* ed. by Clédat, Paris, 1887), contain very inadequate information concerning their metaphysical principles and moral practice. What is certain is that, above all, they formed an anti-sacerdotal party in permanent opposition to the Roman Church, and raised a continued protest against the corruption of the clergy of their time. The Albigensian theologians and ascetics, the Cathari or *perfecti,* known in the south of France as *bons hommes* or *bons chrétiens,* were few in number; the mass of believers (*credentes*) were perhaps not initiated into the Catharist doctrine; at all events they were free from all moral prohibition and all religious obligation, on condition that they promised by an act called *convenenza* to become "hereticized" by receiving the *consolamentum,* the baptism of the Spirit, before their death or even *in extremis.*

The first Catharist heretics appeared in Limousin between 1012 and 1020. Protected by William IX., duke of Aquitaine, and soon by a great part of the southern nobility, the movement gained ground in the south, and in 1119 the Council of Toulouse in vain ordered the secular powers to assist the ecclesiastical authority in quelling the heresy. The people were attached to the *bons hommes,* whose asceticism and anti-sacerdotal preaching impressed the masses, and the movement maintained vigorous activity for another hundred years, until Innocent III. ascended the papal throne. At first he tried pacific conversion; but his envoys had to contend not only with the heretics, the nobles who protected them and the people who listened to them and venerated them, but also with the bishops of the district, who rejected the extraordinary authority which the pope had conferred upon his legates. At last (1209) the pope ordered the Cistercians to preach the crusade against the Albigenses. This implacable war, which threw the whole of the nobility of the north of France against that of the south, and destroyed the brilliant Provençal civilization, ended, politically, in the Treaty of Paris (1229), which destroyed the independence of the princes of the south, but did not extinguish the heresy, in spite of the wholesale massacres of heretics during the war. The Inquisition, however, operating unremittingly in the south at Toulouse, Albi and other towns during the whole of the 13th century and a great part of the 14th, succeeded in crushing it. There were indeed some outbursts of rebellion, some fomented by the nobles of Languedoc (1240–42) and others emanating from the people of the towns, who were embittered by confiscations and religious persecutions, but the repressive measures were terrible. In 1245, the royal officers assisting the Inquisition seized the heretical citadel of Montségur, and 200 Cathari were burned in one day. Moreover, the Church decreed severe chastisement against all laymen suspected of sympathy with the heretics (Council of Narbonne, 1235; Bull *Ad extirpanda,* 1252).

Hunted down by the Inquisition and now abandoned by the nobles of the district, the Albigenses became more and more scattered, hiding in the forests and mountains, and only meeting surreptitiously.

The sect, moreover, was exhausted and could find no more adepts in a district which, by fair means or foul, had arrived at a state of peace and political and religious unity.

BIBLIOGRAPHY.—*See* C. Schmidt's *Histoire de la secte des Cathares ou Albigeois* (1849), which is still the most important work on the subject. On the ethics of the Catharists, *see* Jean Guiraud, *Questions d'histoire et d'archéologie chrétienne* (1906); and P. Alphandéry, *Les idées morales chez les hétérodoxes latins au début du XIIIe siècle* (1903). *See* also under CATHARS.

**ALBINO,** a biological term (Lat. *albus,* white) for a pigmentless individual of a pigmented race. Pigmentation depends upon the presence and interaction in the tissues of colour-bases, chromogens, colourless in themselves, and ferments or enzymes which, acting upon the colour-bases, yield coloured products. If, therefore, either of these ingredients of pigmentation is absent from the constitution of an individual, it must perforce remain pigmentless, albinotic, even though in the environment in which it

lives there are agents, such as sunlight, which are known to stimulate the production of pigment in the tissues of animals and plants exposed to their action. An albino is an individual whose tissues lack the power to elaborate either the ferments or the colour-bases.

In man the general colour of the skin ranges from the fair, almost pigmentless, condition of the Scandinavian to the almost ebony blackness of the natives of certain parts of Africa. These differences have been employed in the classification of races into white, yellow, red, brown, and black. The colour of the skin proper is creamy white. To this is added a tinge of yellow due to the presence of a yellow pigment in the skin. A further ingredient is black, due to the presence of minute granules of melanin, itself sepia in colour but, in masses, so completely absorbing the light that it appears black. Lastly, the red colour of the blood circulating in the minute vessels of the skin adds its tint. It is possible, by using a spinning top with a combination of these colours, white, yellow, red, and black in different proportions, to match any particular skin colour, and it is found, when this is done, that in all pigmented skins all these four colours can be identified, and that different proportions of the yellow and the black in combination correspond to different racial skin colorations. The relative proportions of these two pigments vary greatly in different individuals and in different regions of the body of one and the same individual.

Albinism is the condition, as estimated by this test, in which the black pigment is absent and in which the yellow is present only in relatively small amount.

The eyes of the albino are pink, this colour being the red of the blood circulating in the retinal blood vessels, as seen through the transparent tissues in front. The eyes are extremely sensitive to light and so the eyelids are kept partially closed, while blinking and a general wrinkling of the skin around the eyes are associated conditions which give to the albinotic individual a characteristic appearance. The hair on all parts is white, and all tissues, such as the brain and spinal cord, which in the normal individual are more or less pigmented, are in the albino completely devoid of this melanin.

In the normal individual this black pigment would seem to serve a useful purpose. In the case of the pigmented eye, the intensity of the light falling upon the retina is adequately diminished by the absorbing power of the retinal pigment, and this same melanin in the skin and hair, it is assumed with reason, protects the individual from the rays of the sun in tropical climes. The albino is seriously embarrassed in consequence of its deficiency, the albino animal much less so than the plant, however. Commonly in the breeding of corn or sorghum, when the self-fertilized seeds from an apparently normal green plant are sown, it is found that amongst the seedlings a number of spindling white plants make their appearance only to wither. They die because they lack the pigment chlorophyll, so essential in the manufacture of food, and therefore in the life of the plant. When the seeds of such an albino-producing plant are carefully sown and the number of chlorophyll-possessing and chlorophyll-lacking seedlings are counted, it is found that the greens outnumber the albinos by about three to one. From this it is known that the parent plant was heterozygous for its character green, that albinism in plants as in animals behaves in inheritance as a simple Mendelian recessive, and that in the case of these plants this character in the homozygous condition (*see* MENDELISM) is lethal, since in the absence of chlorophyll the plant cannot assimilate its food.

Albinism has been recorded in the great majority of the species, breeds, and varieties of domesticated animals and of cultivated plants. There are many records of instances of the condition among wild mammals and birds. In the case of mankind it has been observed in most races and probably occurs in all. Its frequency is not known, but it is estimated at perhaps one in 10,000. To-day it is possibly most frequent among the Indians of Arizona and Mexico. Whatever may be the exact frequency of the albinotic in a species, it is certain, since the condition behaves as a Mendelian recessive, that there are far more "carriers" than affected individuals in any race in which albinos appear, and that though originally the condition made its appearance as a "sport" or mutation, resulting from some definite change in the hereditary material of some one individual, since that time its reappearance in the stock is the result of the shuffling and reshuffling of the hereditary factors in their transmission from generation to generation and of the matings of apparently normal individuals who, however, are heterozygous for this particular character, not showing the taint but carrying it and transmitting it to their progeny.

The differently coloured races of a species all have albinotic strains and these may each possess the colour-bases or the ferments of the particular race to which it belongs. Albinos are all alike in that they are unpigmented, but they differ remarkably in respect of their unexpressed pigmentation. Properly planned breeding experimentation reveals the hidden. Pigmented races are not coloured uniformly: there is always some suggestion of a differential regional distribution of pigment, some indication of a pattern, and breeding experimentation has shown that the hereditary factors for the different patterns are transmitted from one generation to another quite independently of those which relate to the actual colour of the skin or coat. Thus it is that an albino that cannot exhibit a pattern because it has no colour can possess in its hereditary constitution factors for one or other of the various patterns. It is known, for example, that when a pure-bred self-coloured mouse is mated with an albino, the pattern of the coats of the offspring is determined by hereditary factors that are known to be absent from the self-coloured stock and to be present in the stock out of which the albino was derived.

So far, complete albinism only has been discussed. Partial albinism is also known, and a study of this condition reveals the fact that the interaction of colour-base and colour-developer is conditioned by such agencies as temperature. The Himalayan rabbit is an excellent example of partial albinism. In this breed the eye is pink and the fur of the body is unpigmented, but the ears, legs, tail, and nose are black. It has been shown that if an area of the white-furred body is shaved and the animal kept in the cold (5–9°C) the new fur that grows is black, whereas if the animal is kept in a warmed room, the new fur is white as before. The baby coat of the Himalayan is all white and the pattern develops after a few weeks when the young are moving freely about. But if the naked baby rabbit is taken from the rest for about ten minutes on two successive days and exposed to a temperature of about 17°C, and especially if it is sponged with cold water, the fur when it is developed later is black all over the body. It follows that the essential ingredients for pigmentation are present in all parts of the skin but that ordinarily the pigment is elaborated only in certain well-defined areas. The Himalayan is a self-coloured race, but the power to elaborate pigment at ordinary temperatures differs in different regions of the body, certain areas being albinotic because normally the temperature of these parts is not that at which the enzyme and colour-base which are undoubtedly present can in their interaction yield pigment.

In certain animals such as the arctic fox, the stoat or ermine, and several hares, and in certain birds, the ptarmigan for example, the pigmented pelage or plumage of the summer and autumn is replaced in the winter by a white one. In the case of the hare, it is held by some that the autumn coat is moulted completely and that the winter coat is a new growth; others hold that there is no moulting but that the autumn coat itself becomes unpigmented; still others are of the opinion that both processes are involved, a whitening of the old fibres and a new growth of non-pigmented fibres. In the ptarmigan the pigmented feathers certainly become white. It is probable that in the hare and similar forms the whiteness is due to the presence of air in the pigmented fibres and consequently to the irregular reflection of the light from the surfaces of these air bubbles. In the case of the ptarmigan it is possible that the whiteness of the winter plumage is due to a seasonal increase in the activity of the thyroid gland, for it is established that if the active principle of the thyroid gland is administered to pigmented domestic fowls, the new feathers as they grow tend to be non-pigmented. It has not yet been shown conclusively that

this seasonal change from the pigmented to the non-pigmented condition is to be regarded as an instance of seasonal albinism.

Occasionally albinotic frogs or axolotls are recorded, but it is doubtful whether all these cases are true examples of albinism. It is more probable that they are individuals in which the pituitary gland or hypophysis at the base of the brain is abnormal; for experiment has shown that if this gland is removed from these animals, the pigment cells in their skin no longer expand and that therefore the animals must preforce remain very pale in colour. An injection of the active principle of the gland, pituitrin, turns them coal-black almost at once. (*See* GENETICS; HEREDITY; COLOURS OF ANIMALS; MELANISM.)

**ALBINOVANUS PEDO,** Roman poet, flourished during the Augustan age. He wrote a Theseis, referred to in a letter from his friend Ovid (*Ex Ponto*, iv. 10), epigrams which are commended by Martial (ii. 77, v. 5) and an epic poem (*cf.* Quintilian x. i. 90) on the exploits of Germanicus under whom he probably served (Tac. *Ann.*, i. 60). This may have been used as a source by Tacitus. All that remains of his works is a beautiful fragment, preserved in the *Suasoriae* (i. 15) of Seneca, describing the voyage of Germanicus (A.D. 16) through the river Ems to the Northern Ocean. Three elegies were formerly attributed to Pedo by Scaliger; two on the death of Maecenas (*In Obitum Maecenatis* and *De Verbis Maecenatis moribundi*), and one addressed to Livia (*Consolatio ad Liviam de Morte Drusi* or *Epicēdion Drusi*, usually printed with Ovid's works); but it is now generally agreed that they are not by Pedo. The *Consolatio* has been put down as the work of a 15th century Italian imitator, there being no mss. and no trace of the poem before the publication of the *edito princeps* of Ovid in 1471. There is an English verse translation of the elegies by Plumptre (1907).

*See* Haupt, *Opuscula*, i. (1875); Bährens, *Poetae Latini Minores* (1879) and *Fragmenta Poetarum Latinorum* (1886); Haube, *Beitrag zur Kenntnis des Albinovanus Pedo* (1880).

**ALBINUS, BERNARD SIEGFRIED** (1697–1770), was born at Frankfurt-on-the-Oder, and from 1718 to his death on Sept. 9, 1770, occupied the chair of anatomy, surgery and medicine at Leyden. He was the first to show by injections the connection of the vascular systems of the mother and the foetus. He also edited with Boerhaave the works of Vesalius and of Harvey. But he is chiefly famed for the excellent drawings in his *Tabula sceleti et musculorum corporis humani* (Leyden, 1747). His *De ossibus corporis humani ad auditores suos libellus* appeared at Leyden, 1726.

**ALBION,** the most ancient name of the British Isles, generally restricted to England (in Ptolemy Ἀλουίων; Lat. *Albion*, Pliny 4, 16 [30], 102). The name is perhaps Celtic but the Romans connected it with *albus*, white, in reference to the chalk-cliffs of Dover, and A. Holder (*Alt-Keltischer Sprachschatz*, 1896) translates it *Weissland*, "white-land." The early writer (6th century B.C.) whose *Periplus* is translated by Avienus (end of 4th century A.D.) does not use the name Britannia; he speaks of νῆσος Ἰέρνων καὶ Ἀλβιόνων ("island of the Ierni and the Albiones"). So Pytheas of Massilia (4th century B.C.) speaks of Ἄλβιον and Ἰέρνη.

**ALBION,** a city of Calhoun county, Mich., U.S., on the Kalamazoo river, 18 mi. W. of Jackson. It is on the Michigan Central railway, and is connected by buses with cities as far north as Grand Rapids and Owosso. The population was 10,395 in 1950 and was 8,345 in 1940 by the federal census. It has 16 factories. On a commanding site in the east part of the city is Albion college (Methodist Episcopal; coeducational), which has an enrolment of about 1,200 students. Albion was settled in 1831, incorporated as a village in 1866 and chartered as a city in 1885. A mayor-commission form of government was adopted by the city.

**ALBITE:** *see* FELSPAR.

**ALBOCARBON** or WHITE CARBON: *see* NAPHTHALENE.

**ALBOIN** (d. 573), king of the Lombards and barbarian conqueror of northern Italy, succeeded his father Audoin about 565. The Lombards at that time occupied Noricum and Pannonia, and were engaged in constant war with the Gepidae. Alboin obtained the alliance of the Avars, and with their help destroyed the Gepidae, slew their king, Cunimund, in battle and married his daughter, Rosamund. On April 1, 568, Alboin had assembled his people with a great number of allies, among them 20,000 Saxons, to cross the Alps and form a new settlement in Italy. There appears to be no truth in the legend that the Lombards were invited to attack Italy by the Byzantine general Narses. This was in effect a migration rather than a mere invasion The Roman defenses were overrun, Milan was occupied (Sept. 4, 569) and Pavia was invested. Lombard rule was established in northern Italy. But Alboin was murdered in 573 at the instigation of Rosamund, whom Alboin had insulted, so the story goes, by making her drink wine from her father's skull.

The authorities for the history of Alboin are Procopius, Paulus Diaconus and Agnellus (in his history of the church of Ravenna).

*See* Thomas Hodgkin, *Italy and Her Invaders*, vol. v (1916).

**ALBONI, MARIETTA** (1823–1894), Italian opera singer, was born at Cesena, Romagna, and studied at Bologna, where she became a pupil of G. A. Rossini. She had a magnificent contralto voice, and made her first appearance at La Scala, Milan, in 1843. In England her reputation was established by her appearance at Covent garden in 1847, and she had brilliant success both in Europe and in the United States. She lived in Paris from 1866 onward, and died at Ville d'Avray in 1894.

**ALBORADA** (*Span.*) signifies strictly a sunrise song or morning serenade akin to the French *aubade* (*q.v.*) but is now applied to a particular kind of instrumental music of a popular type to be heard in certain parts of Spain, the instruments employed being generally the bagpipes and side drum.

**ALBORNOZ, GIL ALVAREZ DE,** Spanish cardinal, was born at Cuenca early in the 14th century and died at Viterbo in 1367. He was made archbishop of Toledo in 1337 and cardinal in 1350. In 1353 Innocent VI sent him from Avignon as legate into Italy with a mission to secure the restoration of the papal authority in the states of the church. By 1362 he had paved the way for the return of Urban V to Rome. As legate, Albornoz showed himself to be an astute manager of men and an effective fighter. He began by making use of Cola di Rienzi, whose release from prison at Avignon he secured. After the murder of the tribune in 1354 Albornoz pursued his task of restoring the pope's authority by intrigue and force. A work by Albornoz on the constitution of the church of Rome, first printed at Jesi in 1473, is now very rare.

BIBLIOGRAPHY.—"De Vita et Rebus Gestis Aegidii Albornotii," in J. G. de Sepulveda, *Opera Omnia*, vol. iv (1780); H. J. Wurm, *Cardenal Albornoz der zweite Begründer des Kirchenstaates* (1892).

**ALBRECHT,** the German form of Albert (*q.v.*).

**ALBRECHTSBERGER, JOHANN GEORG** (1736–1809), famous Austrian musical theorist and teacher, was born at Kloster-Neuburg, and died in Vienna. He studied composition under the court organist, Mann, and became one of the most learned and skilful contrapuntists of his age. In 1772 he was appointed organist to the court of Vienna, and in 1792 *Kapellmeister* of St. Stephen's cathedral. His fame attracted a large number of pupils, among whom were Beethoven, Johann Hummel and Ignaz Moscheles. His compositions, consisting of preludes, fugues and sonatas for the piano and organ, string quartets, etc., are of small importance, and most of them exist only in manuscript, being preserved in the library of the Vienna Gesellschaft der Musikfreunde. In 1790 he published at Leipzig his *Gründliche Anweisung zur Komposition*. A collection of his writings on harmony, in three volumes, was published under the care of his pupil Ignaz von Seyfried (1776–1841) in 1826 (English version 1855).

**ALBRET,** the name of a powerful French family, originating in Labrit, a small village in the Landes of Gascony, on the main road from Bordeaux to Dax and to Bayonne, which it owned in the 10th century. The lord of Albret spread his power by degrees over the surrounding country, obtaining many lordships in Bazadais, Condomois, Bordelais and the countries of the Adour. The family of Albret was divided between several branches. The most powerful of these branches, the eldest, played an important part during the Hundred Years' War and at the beginning of the modern period. Arnaud-Amanieu fought the English troops in Guienne victoriously after 1369 and married Margaret of Bourbon, King Charles V's sister-in-law. His son Charles became constable of France, but was killed at the battle of Agincourt in 1415. Family alliances caused Alain d'Albret, the Great, to be one of the most powerful French lords at the end of the 15th century, and the power of his house was still further increased in the 16th: its head became king of Navarre and prince of Bearn through the marriage of Jean d'Albret, Alain's son, to Catherine of Foix-Grailly; and its patrimonial lands were raised to the rank of duchy (1555). Lastly, a great-granddaughter of Alain the Great, Jeanne, married Antoine de Bourbon; and their son, after the dynasty of the Valois had ceased to be, became king of France as Henry IV.

**ALBUERA, LA** (or ALBUHERA), a small village of Spain, in the province of Badajoz, 13 mi. S.E. of the town of that name, insignificant in itself but celebrated because of the victory gained there on May 16, 1811, by the British, Portuguese and Spaniards, under Viscount Beresford, over the French army commanded by Marshal N. J. de Dieu Soult. Pop. (1940) 1,909.

After Portugal had been cleared of the French invading army under André Masséna, Wellington sought to secure his position by recovering the frontier fortresses. He himself invested Almeida while Beresford was sent, with 10,000 Spaniards, 9,000 Portuguese and 9,000 British only, to lay siege to Badajoz. But the latter was hardly in position before Soult moved upon him from the south with 27,000 veterans. Beresford took up a covering position at Albuera, astride the road to Badajoz, but his dispositions were faulty and Masséna, feinting at a direct thrust down the road, made a concealed manoeuvre round the allied right flank. There the Spanish were cut to pieces or dispersed, a British brigade, hurrying to their aid, was annihilated by the French cavalry, and only a thin line of 1,800 British "redcoats" strung out on a ridge intervened between the French mass of manoeuvre and complete victory. Thin as it was, being a line, it overlapped the front of the massed French columns, and thus gained full value from its fire. For half an hour both sides poured a heavy musketry fire into each other's ranks at point-blank range, and then the nerves of the French snapped under the exorbitant toll, and their columns rolled back down the slopes, gaining momentum as they went until their retirement became a rout. The French losses were about 8,000, and those of the British 4,000 in all, while the Spaniards lost 1,400. Strategically, Beresford's decision to fight was a mistake, for the siege had already been abandoned on Soult's approach; it exposed him to disaster when isolated, and even as it was the losses grievously impaired Wellington's strength. But morally, it had a vital influence on subsequent encounters.

**ALBUFERA DE VALENCIA,** lagoon, 7 mi. S. of Valencia in Spain, about 12 mi. long, 14 mi. broad and 12 ft. deep (max.), with a narrow outlet to the sea under control. It is rich in fish and wild fowl; rice is grown around it. Napoleon made Marshal L. G. Suchet duke of Albufera (1812) after the conquest of Valencia. After the battle of Vittoria (1813) he lost the domain but kept the title. Later, the Spanish nation gave the revenues of Albufera to the duke of Wellington.

**ALBULA PASS,** the principal route from the north to the Upper Engadine in the Grisons. It was used in the 13th century and a carriage road (highest point, 7,595 ft.) was made across it in 1865, but for a long time it was not so much used as the easier and more direct Julier pass (7,504 ft.). The opening of the railway in 1903, however, vastly increased its importance. Starting from Coire the railway follows the Rhine to Reichenau (6¼ mi.), and then the Hinter Rhine to Thusis (10½ mi.). It then runs through the grand Schyn gorge (cut by the Albula torrent) to Tiefenkastell (7½ mi.), where it leaves the Julier road on the right (south) and continues to follow the course of the Albula past Filisur and Bergün (12½ mi.) to the mouth (5,879 ft.) of the tunnel (¾ mi. in length; highest point, 5,987 ft.) which has been pierced below the pass. The railway descends through the Bevers glen to Bevers (2½ mi.), in the Upper Engadine, about 5 mi. below St. Moritz, which is 56 mi. from Coire by this route.

**ALBUM,** in ancient Rome, a board chalked or painted white, on which public notices were inscribed in black. The *Annales Maximi* of the Pontifex Maximus, the annual edicts of the praetor, the lists of senators and jurors, the *Acta Diurna,* etc., were exhibited in this manner. In modern times "album" denotes a book of blank pages in which autographs, sketches or the like are collected. In law, the word is the equivalent of *mailles blanches,* for rent paid in silver ("white") money.

**ALBUMAZAR** or properly ABU-MAASCHOR (805–885), Arab astronomer, was born at Balkh, flourished at Baghdad and died at Wasid in central Asia. His principal works were translated into Latin: *De Magnis Conjunctionibus* (Augsburg, 1489), *Introductorium in Astronomiam* (Venice, 1506) and *Flores Astrologici* (Augsburg, 1488). He maintained in the first that the world, created when the seven planets were in conjunction in the first degree of Aries, will come to an end at a like conjunction in the last degree of Pisces. Albumazar's name is used for the subject of *L'Astrologo* by Gian Battista del Porta (1606), a play which was adapted in *Albumazar* by John Tomkis, played before James I in 1614, revived by J. Dryden in 1748.

**ALBUMINOIDS:** *see* PROTEINS.

**ALBUMINS:** *see* PROTEINS.

**ALBUMINURIA** is the name for the condition in which the urine contains abnormal amounts of albumin. Other proteins and similar compounds such as albuminoses and proteoses occasionally also are found in the urine, and these conditions are called proteinurias. Excessive loss of protein from the body produces serious physiologic changes, and even the loss of small amounts may profoundly affect its metabolism. Therefore, the detection of albumin in the urine is of great diagnostic importance, for its presence may indicate serious pathologic changes in the body, particularly in the kidneys.

The urine may contain red blood cells or haemoglobin, a protein found in red blood cells, but these conditions are not classified as albuminuria. Although the urine normally contains minute amounts of albumin, under normal conditions the kidneys do not permit the escape of appreciable amounts of the blood proteins. However, when the kidneys are diseased, particularly in nephritis (*see* KIDNEY, DISEASES OF), their ability to prevent the loss of protein is seriously affected and these substances appear in readily detectable amounts in the urine. In severe albuminuria the loss of protein may be from one gram to two grams per 100 c.c. of urine.

Protein may also appear in the urine as a result of injury or disease of parts of the urinary tract other than the kidneys, and is referred to as "accidental," "false" or "postrenal" albuminuria.

The diagnosis of albuminuria is made by means of chemical tests which result in precipitation and coagulation of the protein dissolved in the urine. Usually in these tests acids, such as nitric, sulphosalicylic or acetic, are added to the urine, and when this is done, protein, if present in the urine, will form a white or cream-coloured precipitate. The use of heat when the urine is acid also will cause the coagulation of protein. Determination of the amount of protein in the urine requires more elaborate chemical tests which usually depend upon chemical analysis for nitrogen in the precipitated protein.

Under certain conditions, the urine of individuals apparently quite healthy may contain albumin (physiologic albuminuria). The most common causes are strenuous muscular exercise, excessive protein in the diet or exposure to cold. Protein is also commonly found in the urine of infants and in urine in the later stages of pregnancy. The appearance of albuminuria may be intermittent (paroxysmal albuminuria) and without obvious cause. A special example of physiologic albuminuria is orthostatic or postural albuminuria, which dis-

appears when the patient remains in bed but reappears when the patient gets up.

The chief significance of albuminuria is in reference to nephritis in which, characteristically, albumin appears in the urine. Frequently, however, during the course of the disease, protein is absent and a careful study is necessary in order to evaluate properly the urinary findings. Repeated tests are usually necessary before the signs and symptoms of the patient can be correlated with the presence or absence of albuminuria.

A special proteose, known as Bence Jones protein, may rarely be found in the urine. It occurs in connection with certain diseases, such as a cancer of the bone called multiple myeloma (*see* CANCER), and similar proteoses may also be found in the urine of persons ill with leukemia, osteomalacia and myxoedema. The presence of Bence Jones protein in the urine can be determined because, unlike albumin, the white precipitate which forms in the presence of heat and acetic acid at 60° C. dissolves when the temperature is raised to 100° C., again to reappear when the mixture is cooled. Albumin remains in the precipitated form at the temperature of 100° C.

The presence of albuminuria is so significant and serious that insurance companies usually will not insure persons who have this condition, although in the light of present knowledge of transient and physiologic albuminuria a more lenient attitude on the part of insurance companies is evident. (T. B. M.)

**ALBUQUERQUE, ALPHONSO D'** (in old Portuguese AFFONSO D'ALBOQUERQUE), (1453–1515), surnamed THE GREAT, and THE PORTUGUESE MARS, was born in 1453 at Alexandria, near Lisbon, and educated at the court of Alphonso V. In 1503 he set out on his first expedition to the east. He sailed round the Cape of Good Hope to India, where he obtained from the king of Cochin permission to build a Portuguese fort. He returned home in July 1504, and King Emmanuel gave him the command of a squadron of five vessels in the fleet of 16 which sailed for India in 1506 under Tristão da Cunha. After a series of attacks on the Arab cities on the east coast of Africa, Albuquerque separated from Da Cunha and captured (Sept. 1507) the island of Ormuz, in the Persian gulf, which was then one of the chief centres of commerce in the east. He was unable long to maintain his position.

With his squadron increased by three vessels, he reached the Malabar coast at the close of 1508, and produced a commission from the king empowering him to supersede the governor Francisco de Almeida. The governor's reply was imprisonment, from which Albuquerque was released only on the arrival of the grand marshal of Portugal with a large fleet. An unsuccessful attack upon Calicut in Jan. 1510 was immediately followed by the investment and capture of Goa. Albuquerque abandoned the town in August, to return with the reinforcements in November, when he obtained undisputed possession. He next directed his forces against Malacca, which he subdued after a severe struggle. He remained in the town nearly a year to consolidate the position. In 1512 he sailed for the coast of Malabar. On the voyage, Albuquerque's vessel, the "Flor de la Mar," which carried the treasure he had amassed in his conquests, was wrecked, and he himself barely escaped with his life. In September of the same year he arrived at Goa, where he quickly suppressed a serious revolt headed by Idalcan.

Albuquerque had been for some time under orders from the home government to undertake an expedition to the Red sea, in order to secure that channel of communication exclusively to Portugal. He accordingly laid siege to Aden in 1513, but was repulsed; a voyage into the Red sea, the first ever made by a European fleet, led to no substantial results. His last success was the recapture in 1515 of the island of Ormuz, which remained in the possession of the Portuguese until 1622. Albuquerque had several enemies at the Portuguese court, and on his return from Ormuz, at the entrance of the harbour of Goa, he met a vessel from Europe bearing dispatches announcing that he was superseded by his personal enemy, Soarez. He died at sea on Dec. 16, 1515. Before his death he wrote a letter to the king in dignified and affecting terms, vindicating his conduct and claiming for his son the honours and rewards due to himself.

His body was buried at Goa, and it is, perhaps, the most convincing proof possible of the justice of his administration that, many years after, Moslems and Hindus used to go to his tomb to invoke protection against the injustice of his successors. His natural son Affonso published a selection from his father's papers under the title *Commentarios do Grande Affonso d'Alboquerque.*

BIBLIOGRAPHY.—*See* the *Cartas de Albuquerque,* vol. i, published by the Lisbon academy (1884); also Morse Stephens, *Life of Albuquerque,* in the "Rulers of India" series. An article in the *Bolitim* of the Lisbon Geographical society (January to June 1902) on "O antigo Imperialismo portuguez, etc.," has especial reference to Albuquerque.

**ALBUQUERQUE, MATHIAS DE** (d. 1647), Portuguese general, was governor of Pernambuco in 1624 and, after the Dutch captured Bahia, governor general of North Brazil. As governor in Pernambuco again in 1629 he had to meet the Dutch invasion of that province, and in 1630 was forced to surrender Olinda and the forts of the Recif. Sent back to Portugal in disgrace in 1635, he took part later in the Portuguese War of Liberation, defeating the Spaniards under Mölingen at Montijo, on May 26, 1644, and thereby earning the title of count of Allegrete. He died at Lisbon June 9, 1647.

**ALBUQUERQUE,** the largest city of New Mexico, U.S., is in the valley of the Rio Grande, at an altitude of 5,196 ft., in the approximate centre of the state. It is the county seat of Bernalillo county and a division point on the Santa Fe railway. It is on federal highways 66 and 85, and is also served by bus and air lines. Population by the federal census of 1950 was 97,012; in 1940 it was 35,449. The bracing climate and the large proportion of sunshiny days have given it a reputation as a health resort, and it has several private sanatoria for the treatment of tuberculosis.

Albuquerque distributes vast quantities of supplies and material of all kinds to the sheep and cattle industry, to mining and timbering operations and to smaller cities and towns throughout the state. A large air force base (Kirtland field) is located there, as is Sandia base of the Atomic Energy commission.

Among items manufactured and processed in Albuquerque are brick and tile, concrete pipe, truck bodies, trailers, furniture, chemicals, clothing, batteries, brushes, caskets, precision machinery, playground equipment, leather goods, fabricated iron and steel, felt and cloth emblems, flour, candy, ice cream and dairy products, lumber, mattresses, meat products, metal tanks and culverts, signs, optical goods, sashes and doors, tents and awnings. In addition, the Santa Fe railway maintains large railroad shops.

Albuquerque is the seat of the University of New Mexico (opened in 1892), with a registration of approximately 4,600 students in 1951. An adaptation of the pueblo style of architecture has been used in the university buildings.

Within easy motoring distance are the Indian pueblos of San Felipe, which has a church built by Fray Cristóbal de Quinones (d. 1609); of Isleta and Santo Domingo, where fine ceremonial dances are performed; of picturesque Laguna, with its interesting mission church; and of Acoma, perched on a precipitous mesa 357 ft. high, which was already very old when Fray Marcos arrived in 1539.

The "old town," which lies along the river bank, was founded in 1706 by Don Francisco Cuervo y Valdes, and named by him after the duke of Alburquerque, a viceroy of New Spain. The duke ordered the name to be changed to San Felipe de Alburquerque, as a compliment to the reigning king. With the passage of time it became reduced to one word, and that word lost one of its "r's."

The mission church of San Felipe de Neri (1735) is still standing, and the entire district keeps its old Spanish character. It was an important centre in the Spanish and the Mexican occupations.

During the Civil War it was occupied by Confederate troops (Feb. 1862) under Gen. Henry Hopkins Sibley, who soon afterward advanced into northern New Mexico. In his retreat into Texas he made a stand there, on April 8, 1862, against a detachment of Union troops commanded by Col. R. S. Canby.

The modern city was founded in 1879; the railway reached it in 1880; by 1890 it had a population of 3,785. A city-manager form of government was adopted later.

**ALBURY,** a small country town of rising importance in Goulburn county, New South Wales, Austr. Situated at an elevation of 542 ft. on the right (north) bank of the river Murray,

approximately 1,470 mi. from its mouth, Albury marks the head of possible navigation (July-December) on this stream, though infrequent river steamers normally ply only as far as Echuca. Its position, again, on the western flank of the eastern highlands, not far from the point of debouchment of the Murray, and in the general line of connection between Melbourne and Sydney, constitutes Albury a crossing-place of some importance. As a fording point it has figured in the history of Australian exploration. In 1883 the Victoria and New South Wales railway systems were connected at this point, and Albury is now a bridge town on the main line linking Victoria and New South Wales (Albury–Sydney *c.* 350 mi., Albury–Melbourne *c.* 190 mi.), and also the eastern and western portions of the continent (Transcontinental line, Fremantle and Perth-Brisbane). The river is crossed by means of an iron bridge from Wodonga on the Victorian side, and here also is a break of gauge (Victorian system: 5′ 3″; N.S.W.: 4′ 8½″). A little above Albury is the confluence of the Murray with its tributary the Mitta Mitta. Albury, therefore, figures in the now historic River Murray Agreement (1914), and it has acquired further considerable importance as a result of the execution of the schemes under that agreement, such as the nearby Hume reservoir. Albury, which has a mean annual temp. of 60.7°, mean annual rainfall of 27.65 in., of which 18.9 in. falls in the seven months, April–October, is the centre and virtual capital of the eastern Riverina, a rich agricultural and pastoral district producing wheat, fruit and sheep. Albury became a municipality in 1859, and has shown a steady rise in population (1891, 5,447; 1921, 7,752; 1933, 10,543).

**ALCAEUS** or **ALKAIOS** (*c.* 600 B.C.), Greek poet, holds second place in the Alexandrian lyric canon. He was a contemporary of Sappho, and a member of one of the noble families of Mitylene.

In the war against the Athenians (606), he fled from battle with the loss of his shield. His political enemies drove him into exile, but towards the end of his life he is said to have been pardoned by Pittacus. His poems, which were written in the Aeolic dialect, included hymns; political poems (*stasiōtica*), in which he abused the tyrants, his political enemies; love-songs; and drinking-songs. He seems to have invented the Alcaic metre, and was regarded as a model by Horace.

*See* Bergk, *Poetae Lyrici Graeci* (1882); also *The Songs of Alcaeus*, by J. Easby-Smith (Washington, 1901); Plehn, *Lesbiacorum Liber* (1826); Flach, *Geschichte der griechischen Lyrik* (1883–84); Farnell, *Greek Lyric Poets* (1891). New fragments edited by J. M. Edmonds (1909). *See* also Edgar Lobel, Ἀλκαίου Μέλη, *the Fragments of the Lyrical Poems of Alcaeus* (Oxford, 1928).

**ALCAICS,** the name of several lyric verses, from Alcaeus of Lesbos, their supposed inventor. They comprise:

(1) Alcaic hendecasyllable: ⏑ – ⏑ – ⏑ – ⏑ ⏑ – ⏑ –
Examples: Latin, "odi profanum volgus et arceo."
English imitation, "O mighty-mouthed inventor of harmonies."

(2) Alcaic decasyllable: – ⏑ ⏑ – ⏑ ⏑ – ⏑ – ⏑
Examples: Latin, "virginibus puerisque canto."
English imitation, "Milton, a name to resound for ages."

(3) Alcaic enneasyllable: ⏑ – ⏑ ⏑ – ⏑ ⏑ – ⏑
Examples: Latin, "audita Musarum sacerdos."
English imitation, "God-gifted organ-voice of England."

The Alcaic stanza consists of (1) twice repeated, followed by (3) and then (2), once each. It was a great favourite, not only of its inventor, but of Horace, who made some very slight modifications to adapt it to Latin. In modern languages it has been imitated by Tennyson (from whom the above English lines are taken) and occasionally by poets in other languages, but never with much success.

The manner in which the lines should be divided into feet is, in this as in all "Aeolic" metres, a highly controversial point.

**ALCAIDE,** a Spanish title meaning the governor of a fortress (Arabic *al-quāid*).

**ALCALÁ** (Moorish *al kala*, the "Fortress" or "Castle"), the name of thirteen Spanish towns, all founded or named by the Moors. Alcalá de Henares, pop. (1940) 18,013, is separately described on account of its historical importance. Alcalá la Real (8,437), a picturesque town with a fine abbey, is situated in the mountainous south-west part of Jaén. Its distinctive name *la Real*, "the Royal," was conferred in memory of its capture by Alphonso XI. of Leon in 1340. In 1810 the French under Count Sebastiani here defeated the Spaniards. Alcalá de los Gazules (6,135), on the river Barbate, in the province of Cadiz, trades in cork and agricultural produce. Alcalá de Guadaira (17,758), on the river Guadaira, near Seville, is popularly called Alcalá de los Panaderos, or "Alcalá of the Bakers," because it supplies Seville with large quantities of bread; it also manufactures for export the best "Seville oil."

**ALCALÁ DE HENARES,** Spain, 17 mi. E.N.E. of Madrid, on the river Henares. Pop. (1940) 18,013 (mun., 18,419). Alcalá de Henares contains a military academy. The town has been identified with the Roman *Complutum*, destroyed about 1000, and rebuilt by the Moors in 1083. Later its university, founded by Cardinal Jimenes de Cisneros in 1510, was second only to that of Salamanca. Here the famous *Complutensian Polyglot* Bible was prepared from 1514 to 1517. The college of San Ildefonso completed in 1583, was the chief university building. Its modernized Gothic church, the Colegiata, contains the 16th century marble monument of Jimenes (d. 1517) and a fine reredos.

On the removal of the university to Madrid in 1836 the town declined, and the university buildings became archives of state departments and of the Inquisition. One of the principal libraries is the former palace of the archbishops of Toledo.

BIBLIOGRAPHY.—H. Florez and others, "Annales Complutenses" and "Chronicon Complutense" in *España Sagrada* (1754–1879); Galo Sanchez, *Fueros Castellanos de Soria y Alcalá de Henares* (1919).

**ALCALDE,** the title in Spanish for officials of somewhat varied functions in which, however, there is always a judicial element. *Alcalde de corte* was a judge of the palace court, having jurisdiction in and about the residence of the king. But the title is now exclusively used for the mayor of a town or village who discharges the functions of a justice of the peace. The title of *alcalde* must be carefully distinguished from *alcaide* (*q.v.*) which means the governor of a fortress.

**ALCAMENES,** a Greek sculptor of Lemnos and Athens. He was a younger contemporary of Pheidias and noted for the delicacy and finish of his works, among which a Hephaestus and an Aphrodite "of the Gardens" were conspicuous. Pausanias says (v. 10, 8) that he was the author of one of the pediments of the temple of Zeus at Olympia (*see* GREEK ART), but this seems a chronological and stylistic impossibility. At Pergamum there was discovered in 1903 a copy of the head of the Hermes "Propylaeus" of Alcamenes (*Athenische Mittheilungen*, 1904, p. 180). It is safer, however, to judge him by the sculptural decoration of the Parthenon, in which he must almost certainly have taken a share under the direction of Pheidias.

**ALCAMO,** province of Trapani, Sicily, 24 mi. W.S.W. of Palermo direct (51½ mi. by rail). Pop. (1936) 38,129 (town), 38,396 (commune). The Saracenic chief Al-Kamuk erected the castle (A.D. 828), considerably altered since. Frederick II removed the site lower down (1233). The surrounding district is very fertile.

**ALCÂNTARA,** a small seaport of Brazil, in the State of Maranhão, on the west shore of the bay of São Marcos, 16 mi. from the city of São Luiz by water. It has a fairly good harbour, and excellent cotton and rice are grown in the vicinity and shipped from the port.

**ALCÁNTARA,** western Spain, province of Cáceres, on a rocky height on the left bank of the river Tagus, 7 mi. from the Portuguese frontier. Pop. (1940) 4,404 (mun., 4,657). Alcántara (in Arab. "the bridge") owes its name to the magnificent Roman bridge which spans the Tagus on the northwest, built about A.D. 105, in honour of the emperor Trajan and at the cost of eleven Lusitanian communities. A small temple, dedicated to Trajan and other deified emperors, adjoined the bridge on the left bank. Though it has been identified with Norba Caesarea and with Interamnium, it is doubtful whether there was a Roman town here. It became famous about 1215 as the stronghold of the knights of Alcántara, many of whose grand masters lie buried in the 13th-century Gothic church.

**ALCAVALA,** a duty charged in Spain and its colonies until the invasion of Napoleon (from Arab. *al-quabalah,* "tax," *quabala,* "to receive"; *cf.* Fr. *gabelle*). Originally imposed in 1341 by Alphonso XI. to secure freedom from the Moors, it was an *ad valorem* tax of 10%, increased afterwards to 14%, on the selling price of all commodities, whether raw or manufactured, and chargeable as often as they were sold or exchanged. This was a monstrous imposition which subjected every farmer, manufacturer, merchant and shopkeeper to the continual visits and examination of the tax-gatherers, whose number was necessarily very great.

**ALCAZAR, B. DEL** (1530–1606), Spanish poet, was born at Seville. He served under the Marqués de Santa Cruz and afterwards in the households of the Duque de Alcala and of the Conde de Gelves. Alcazar belonged to the Italianate school and modelled himself on Martial. The grace and cynicism of Baltasar del Alcazar are manifested in his *Poesias* (ed. F. R. Marin, 1910).

**ALCÁZAR DE SAN JUAN** or **ALCÁZAR,** Spain, province of Ciudad Real, and an important railway junction, where the lines to the east and south-east diverge from the main line to Andalusia. Pop. (1940) 23,083 (mun., 26,141). Alcázar trades in wine and manufactures soap, gunpowder, chocolate and inlaid daggers. It is sometimes identified with the Roman *Alce,* captured by Tiberius Sempronius Gracchus in 180 B.C. It derives its name from its mediaeval Moorish castle (*al-kasr*), afterwards garrisoned by the knights of St. John. The entire district is associated with Cervantes and with the action of *Don Quixote* (El Toboso, 12 mi. E.N.E.; Argamasilla de Alba, 22 mi. S.E.). Local antiquaries even identify the knight with Don Rodrigo de Pacheco, whose portrait adorns the parish church.

**ALCESTER, FREDERICK BEAUCHAMP PAGET SEYMOUR,** BARON (1821–95), British admiral, was born April 12, 1821. Entering the navy in 1834, he served in the Mediterranean and the Pacific, was for three years flag-lieutenant to his uncle Sir George Seymour, and was promoted to be commander in 1847. He had a distinguished naval record and held a series of high commands. In 1880–83 he was commander-in-chief of the fleet in the Mediterranean, and in 1880 had also the chief command of the European squadron sent to the coast of Albania as a demonstration to the Porte to cede Dulcigno to Montenegro. In July 1882 Admiral Seymour commanded at the bombardment of Alexandria and in the subsequent operations on the coast of Egypt, for which service he was raised to the peerage, received a parliamentary grant of £25,000, the freedom of the City of London and a sword of honour. He retired from the service in 1886, and died in London, March 30, 1895.

**ALCESTER** (aul'stur), a market-town, Warwickshire, England, 16 mi. W.S.W. of Warwick on the G.W. and L.M.S. railways. Population of rural district (1938) 11,610. It is situated at the junction of the small stream Alne with the Arrow, a northern tributary of the Avon.

The name (Alnecestre, Alyncester) signifies "the camp on the Alne." A small Romano-British town or village was situated here on the road which ran from Derby to join the Fosse Way near Cirencester. Pavements, potsherds, coins and burials have been found, but nothing to indicate an important station. No written document relating to Alcester exists before the reign of Henry I. when it seems to have been a royal borough, but the title of borough soon lapsed. In the reign of Henry III. a moiety of the manor was purchased by Sir Walter Beauchamp, who granted a charter establishing a Tuesday market for corn, cattle and all kinds of merchandise, and also obtained grants of fairs. In 1444 Sir John Beauchamp purchased the remaining moiety of the manor, and was granted an additional fair. From this date the Beauchamps were lords of the whole manor until it passed by female descent to the Grevilles in the reign of Henry VIII. In 1140 a Benedictine monastery was founded here by Ralph Boteler of Oversley, and received the name of the Church of Our Lady of the Isle, owing to its insulation by a moat meeting the River Arrow. The monastery was suppressed among the smaller houses in 1536. Traces of the moat and the foundations are still to be seen in Priory Close. The ancient fairs survived to the end of the 19th century. The church of St. Nicholas was rebuilt in 1734.

The manufacture of needles, which employed nearly 1,000 hands in 1830, is now unimportant, having been absorbed into the centre of the industry at Redditch, but needle stamping and scouring are carried on. There are implement and cycle works, metal glazing and polishing being a special feature.

**ALCESTIS,** in Greek legend, the wife of Admetus (*q.v.*).

**ALCHEMY.** In the narrow sense of the word, alchemy is the pretended art of making gold and silver, or transmuting the base metals into the noble ones. The idea of such transmutation probably arose among the Alexandrian Greeks in the early centuries of the Christian era; thence it passed to the Arabs, by whom it was transmitted to western Europe. Its realization was a leading aim of chemical workers down to the time of Paracelsus and even later. Alchemy in its wider and truer significance stands for the chemistry of the middle ages. The idea of transmutation, in the country of its origin, had a philosophical basis, and was linked up with the Greek theories of matter there current. Thus, by supplying a central philosophical principle, it to some extent unified and focused chemical effort, which previously, so far as it existed at all, had been expended on acquiring empirical acquaintance with a mass of disconnected technical processes. Alchemy in this sense is merely an early phase of the development of systematic chemistry; in Liebig's words, it was "never at any time anything different from chemistry."

Regarding the derivation of the word, there are two main views which agree in holding that it has an Arabic descent, the prefix *al* being the Arabic article. But according to one, the second part of the word comes from the Greek χυμεία, pouring, infusion, used in conjunction with the study of the juices of plants, and thence extended to chemical manipulations in general; this derivation accounts for the old-fashioned spellings "chymist" and "chymistry." The other view traces it to *khem* or *khamé,* hieroglyph *khmi,* which denotes black earth as opposed to barren sand, and occurs in Plutarch as χυμεία. On this derivation alchemy is explained as meaning the "Egyptian art"; *i.e.,* the art of the black land. The first occurrence of the word is said to be in a treatise of Julius Firmicus, an astrological writer of the 4th century, but the prefix *al* there must be the addition of a later copyist. In English, *Piers Plowman* (1362) contains the phrase "experimentis of alconomye," with variants "alkenemye" and "alknamye." The prefix *al* begins to be dropped about the middle of the 16th century.

**Origins of Alchemy.**—Numerous legends cluster round the origin of alchemy. According to one story, it was founded by the Egyptian god Hermes (Thoth), the reputed inventor of the arts and sciences; after him later alchemists called their work the "hermetic art," and the seal of Hermes, which they placed upon their vessels, is the origin of the common phrase "hermetically sealed." Another legend asserts that the fallen angels taught the arts to the women they married, their instruction being recorded in a book called *Chemā.* A similar story appears in the Book of Enoch, and Tertullian has much to say about the wicked angels who revealed to men the knowledge of gold and silver, of lustrous stones and of the power of herbs, and who introduced the arts of astrology and magic upon the earth. Another legend to be found in Arabic sources, asserts that alchemy was revealed by God to Moses and Aaron. But there is some evidence that, in accordance with the strong and constant tradition among the alchemists, the idea of transmutation did originate in Egypt with the Greeks of Alexandria. In the Leyden museum there are a number of papyri which were found in a tomb at Thebes in 1828, written probably in the 3rd century A.D., though their matter is much older. Some are in Greek and demotic, and one, of peculiar interest from the chemical point of view, gives a number of recipes, in Greek, which show a considerable knowledge in the manipulation of base metals to form alloys which simulate gold, and are intended to be used as a workshop manual in the manufacture of imitation jewellery. Possibly this is one of the books about gold and silver of which Diocletian decreed the destruction about A.D. 290. It has been suggested by M. P. E. Berthelot (*q.v.*) that the workers in

these processes, which were a monopoly of the priestly caste and were kept strictly secret, though fully aware that their products were not truly gold, were in time led by their success in deceiving the public to deceive themselves also, and to come to believe that they actually had the power of making gold from substances which were not gold. Philosophical sanction and explanation of this belief was then found by bringing it into relation with the theory of the *prima materia,* which was identical in all bodies but received its actual form by the adjunction of qualities expressed by the Aristotelian elements—earth, air, fire and water. Some support for this view is gained from study of the alchemistical writings of the period. Thus, in the treatise known as *Physica et Mystica* and falsely ascribed to Democritus (such false attributions are a constant feature of the literature of alchemy), various recipes are given for colouring and gilding metals, but the conception of transmutation does not occur. This treatise was probably composed at a date not very different from that of the Leyden papyrus. Later, however, as in the *Commentary* on this work written by Synesius to Dioscorus, priest of Serapis at Alexandria, which probably dates from the end of the 4th century, a changed attitude becomes apparent. The more practical parts of the recipes are obscured or omitted, and the processes for preparing alloys and colouring metals, described in the older treatise, are by a mystical interpretation represented as resulting in real transmutation.

But while there are thus some grounds for supposing that the idea of transmutation grew out of the practical recipes of Alexandrian Egypt, the alchemy which embraced it as a leading principle was also much affected by eastern influences such as magic and astrology. The earliest Greek alchemistical writings abound in references to oriental authorities and traditions. Thus the pseudo-Democritus, who was the reputed author of the *Physica et Mystica,* which itself concludes each of its recipes with a magical formula, was believed to have travelled in Chaldaea, and to have had as his master Ostanes the Mede, a name mentioned several times in the Leyden papyrus, and often by early Christian writers such as Tertullian, St. Cyprian and St. Augustine. The practices of the Persian adepts also are appealed to in the writings of the pseudo-Democritus, and of Zosimus and Synesius. The philosopher's egg, as a symbol of creation, is both Egyptian and Babylonian. In the Greek alchemists it appears as the symbol at once of the art and of the universe, enclosing within itself the four elements. The conception of man, the microcosm, containing in himself all the parts of the universe or macrocosm, is also Babylonian, as again probably is the famous identification of the metals with the planets. Even in the Leyden papyrus the astronomical symbols for the sun and moon are used to denote gold and silver, and in the *Meteorologica* of Olympiodorus lead is attributed to Saturn, iron to Mars, copper to Venus, tin to Hermes (Mercury) and electrum to Jupiter. Similar systems of symbols, but elaborated to include compounds, appear in Greek mss. of the 10th century, preserved in the library of St. Mark's at Venice. Subsequently electrum (an alloy of gold and silver) disappeared as a specific metal, and tin was ascribed to Jupiter instead, the sign of mercury becoming common to the metal and the planet.

**Literature of Alchemy.**—A considerable body of Greek chemical writings is contained in mss. belonging to the various great libraries of Europe, the oldest being that at St. Mark's, just mentioned. The contents of these mss. are all of similar composition, and in Berthelot's opinion represent a collection of treatises made at Constantinople in the 8th or 9th century. The treatises are nearly all anterior to the 7th century, and most appear to belong to the 3rd and 4th centuries; some are the work of authentic authors like Zosimus and Synesius, while others, such as profess to be written by Moses, Democritus, Ostanes, etc., are of clearly fictitious authorship. Some of the same names and the same works can be identified in the lists of the *Kitáb-al-Fihrist* (written by al-Nadim toward the end of the 10th century). But the Arabs did not acquire their knowledge of this literature at first hand. The earliest Hellenic culture in the east was Syrian, and the Arabs made their first acquaintance with Greek chemistry, as with Greek philosophy, mathematics, medicine, etc., by the intermediary of Syriac translations. (*See* ARABIAN PHILOSOPHY and SYRIAC LITERATURE.) Examples of such translations are preserved in mss. at the British museum, partly written in Syriac, partly in Arabic with Syriac characters. In Berthelot's opinion, the Syriac portion represents a compilation of recipes and processes undertaken in the Syrian school of medicine at Baghdad under the Abbasids in the 9th or 10th century, and to a large extent constituted by the earlier translations made by Sergius of Resaena in the 6th century. They contain, under the title *Doctrine of Democritus,* a fairly methodical treatise in ten books comprising the *Argyropoeia* and *Chrysopoeia* of the pseudo-Democritus, with many recipes for colouring metals, making artificial precious stones, effecting the *diplosis* or doubling of metals, etc. They give illustrations of the apparatus employed, and their close relationship to the Greek is attested by the frequent occurrence of Greek words and the fact that the signs and symbols of the Greek alchemists appear almost unchanged. The other portion seems of somewhat later date. Another Syriac ms., in the library of Cambridge university, contains a translation of a work by Zosimus which is so far unknown in the original Greek. Berthelot gives reproductions of the British Museum mss. in vol. ii of *La Chimie au moyen âge.*

Several alchemistical treatises, written in Arabic, exist in manuscript in the National Library at Paris and in the library of the University of Leyden, and have been reproduced by Berthelot, with translations, in vol. iii of *La Chimie au moyen âge.* They fall into two groups: those in one are largely composed of compilations from Greek sources, while those in the other have rather the character of original compositions. Of the first group the most interesting and possibly the oldest is the *Book of Crates;* it is remarkable for containing some of the signs used for the metals by the Greek alchemists, and for giving figures of four pieces of apparatus which closely resemble those depicted in Greek mss., the former being never, and the latter rarely, found in other Arabic mss. Its concluding words suggest that its production was due to Khalid ben Yezid (died in 708), who was a pupil of the Syrian monk Marianus, and according to the *Kitáb-al-Fihrist* was the first Moslem writer on alchemy. The second group consists of a number of treatises professing to be written by Jabir, celebrated in Latin alchemy as Geber (*q.v.*). Internal evidence suggests that they are not all from the same hand or of the same date, but probably they are not earlier than the 9th nor later than the 12th century. The Arabic chroniclers record the names of many other writers on alchemy, among the most famous being Rhazes and Avicenna who were physicians.

But the further development of alchemy took place in the west rather than in the east. With the spread of their empire to Spain the Arabs took with them their knowledge of Greek medicine and science, including alchemy, and thence it passed to the nations of western Europe, through the medium of Latin translations which began about the 11th century. The *Liber de compositione alchemiae,* which professes to be by Morienus—perhaps the same as the Marianus who, according to legend, was the teacher of Khalid—was translated by Robertus Castrensis, who states that he finished the work in 1182. The earlier translations, such as the *Turba Philosophorum* and other works printed in collections like the *Artis auriferae quam chemiam vocant* (1572), *Theatrum chemicum* (1602) and J. J. Manget's *Bibliotheca chemica curiosa* (1702), are confused productions, written in an allegorical style, but full of phrases and even pages taken literally from the Greek alchemists, and citing by name various authorities of Greek alchemy. They were followed by treatises of a different character, clearer in matter, more systematic in arrangement, and reflecting the methods of the scholastic logic. These are farther from the Greek tradition, for although they contain sufficient traces of their ultimate Greek ancestry, their authors do not know the Greeks as masters and cite no Greek names. So far as they are Latin versions of Arabico-Greek treatises, they must have been much remodelled in the course of translation; but there is reason to suppose that many of them, even when pretending to be translations, are really original compositions. It is curious that although we possess a certain number of works on alchemy written in Arabic,
